Schrieffer-Wolff transformation for quantum many-body systems

Sergey Bravyi[*], David P. DiVincenzo[†], and Daniel Loss[‡]

January 20, 2013

Abstract

The Schrieffer-Wolff (SW) method is a version of degenerate perturbation theory in which the low-energy effective Hamiltonian H_{eff} is obtained from the exact Hamiltonian by a unitary transformation decoupling the low-energy and high-energy subspaces. We give a self-contained summary of the SW method with a focus on rigorous results. We begin with an exact definition of the SW transformation in terms of the so-called direct rotation between linear subspaces. From this we obtain elementary proofs of several important properties of H_{eff} such as the linked cluster theorem. We then study the perturbative version of the SW transformation obtained from a Taylor series representation of the direct rotation. Our perturbative approach provides a systematic diagram technique for computing high-order corrections to H_{eff}. We then specialize the SW method to quantum spin lattices with short-range interactions. We establish unitary equivalence between effective low-energy Hamiltonians obtained using two different versions of the SW method studied in the literature. Finally, we derive an upper bound on the precision up to which the ground state energy of the n-th order effective Hamiltonian approximates the exact ground state energy.

1 Introduction

Given a fundamental theory describing a quantum many-body system, one often needs to obtain a concise description of its low-energy dynamics by integrating out high-energy degrees of freedom. The Schrieffer-Wolff (SW) method accomplishes this task by constructing a unitary transformation that decouples the high-energy and low-energy subspaces.

In the present paper we view the SW method as a version of degenerate perturbation theory. It involves a Hamiltonian H_0 describing an unperturbed system, a low-energy subspace $\mathcal{P}_0$ invariant under H_0, and a perturbation ϵV which does not preserve $\mathcal{P}_0$. The goal is to construct an effective Hamiltonian H_{eff} acting only on $\mathcal{P}_0$ such that the spectrum of H_{eff} reproduces eigenvalues of the perturbed Hamiltonian $H_0+\epsilon V$ originating from the low-energy subspace $\mathcal{P}_0$. The SW transformation is a unitary operator U such that the transformed Hamiltonian $U(H_0+\epsilon V)U^\dagger$ preserves $\mathcal{P}_0$. The desired effective Hamiltonian is then defined as the restriction of $U(H_0+\epsilon V)U^\dagger$ onto $\mathcal{P}_0$. An important consideration arising in the context of many-body systems such as molecules or interacting quantum spins is the locality of H_{eff}. In order for the effective Hamiltonian H_{eff} to be usable, it must only involve k-body interactions for some small constant k. We demonstrate that this is indeed the case for the SW method by proving (under certain natural assumptions) that it obeys the so called linked cluster theorem.

The purpose of the present paper is two-fold. First, we give a self-contained summary of the SW method with a focus on rigorous results. A distinct feature of our presentation is the use of both perturbative and exact treatments of the SW transformation. The former is given in terms of the Taylor series and the rules for computing the Taylor coefficients while the latter involves the so called direct rotation between linear subspaces[1]. By combining these different perspectives we are able to obtain elementary proofs of several important properties of the effective Hamiltonian H_{eff} such as its additivity under a disjoint union of non-interacting systems. These properties do not manifest themselves on the level of individual terms in the perturbative expansion which makes their direct proof (by inspection of the Taylor coefficients of H_{eff}) virtually impossible. In addition, our approach provides a systematic diagram technique for computing high-order corrections to H_{eff} which can be readily cast into a computer program for practical calculations.

Our second goal is to specialize the SW method to interacting quantum spin systems. We assume that the unperturbed Hamiltonian H_0 is a sum of single-spin operators such that the low-energy subspace $\mathcal{P}_0$ is a tensor product of single-spin low-energy subspaces. The perturbation V is chosen as a sum of two-spin interactions associated with edges of some fixed interaction graph. We prove that the Taylor series for H_{eff} obeys the so called linked cluster theorem, that is, the m-th order correction to H_{eff} includes only interactions among subsets of spins spanned by connected clusters of at most m edges in the interaction graph (one should keep in mind that the spins acted on by H_{eff} are 'effective spins' described by the low-energy subspaces of the original spins), see Theorem 2 in Section 4.3. It demonstrates that the SW transformation maps a high-energy theory with local interactions to an effective low-energy theory with (approximately) local interactions.

---

[1] The direct rotation can be thought of as a square root of the double reflection operator used in the Grover search algorithm [1].

For macroscopic spin systems the norm of the perturbation $\|\epsilon V\|$ is typically much larger than the spectral gap of H_0 and one should expect level crossings to occur between energy levels from the low-energy and high-energy subspaces. On the other hand, one should expect that for sufficiently small $|\epsilon|$ ground states of $H_0 + \epsilon V$ have most of their weight inside the low-energy subspace $\mathcal{P}_0$. We prove that this is indeed the case for so-called block-diagonal perturbations V, that is, perturbations preserving $\mathcal{P}_0$. Specifically, we prove that the low-energy subspace $\mathcal{P}_0$ contains at least one ground state of $H_0 + \epsilon V$ as long as $|\epsilon| < \epsilon_0$ for some constant ϵ_0 that depends only on the spectral gap of H_0, the degree of the interaction graph, and the strength of spin-spin interactions, see Lemma 4.1 in Section 4.2. In that sense, the ground state of the system has a constant stability radius against block-diagonal perturbations.

The main technical result reported in the paper is a rigorous upper bound on the error δ_m up to which the ground state energy of H_{eff}, truncated at the m_{th} order, approximates the ground state energy of the exact Hamiltonian $H_0 + \epsilon V$, see Theorem 1 in Section 4.5. Specifically, we prove that there exist constants c_m, ϵ_m such that $\delta_m \le c_m N |\epsilon|^{m+1}$ for all $|\epsilon| < \epsilon_m$, where N is the total number of spins. The coefficients c_m and ϵ_m depend only on the degree of the interaction graph, the strength of spin-spin interactions, the spectral gap Δ of the unperturbed Hamiltonian H_0, and the truncation order m. It shows that the approximation error δ_m is extensive (linear in N) for fixed m. On the other hand, δ_m may grow very rapidly as a function of m. Note that our bound holds even in the region of parameters $\|\epsilon V\| \gg \Delta$ where the perturbative series for H_{eff} are expected to be divergent. The proof of the bound on δ_m combines the SW transformation, the linked cluster theorem, and the ground state stability against block-diagonal perturbations.

One undesirable feature of the SW transformation is that its generator $S = \log(U)$ is a highly non-local operator which cannot be written as a sum of local interactions even in the lowest order in ϵ. The fact that locality of the theory does not manifest itself on the level of the generator S can be safely ignored if one is interested only in the final expression for H_{eff}. However the non-local character of S makes it more difficult to prove bounds on the truncation error δ_m. We resolve this problem by employing a different version of the SW method due to Datta et al [2] which we refer to as a *local SW method.* By analogy with the standard SW it defines a unitary transformation U generating an effective low-energy Hamiltonian acting on $\mathcal{P}_0$. The advantage of the local SW transformation is that its generator $S = \log(U)$ has nice locality properties which makes analysis of the truncation error δ_m obtained using the local SW method much easier, see Theorem 3 in Section 4.4. Unfortunately, the local SW transformation does not exist outside the realm of perturbative expansions lacking an 'exact definition' similar to the standard SW. We establish equivalence between the local and the standard versions of the SW method by showing that the corresponding m-th order effective Hamiltonians can be mapped to each other by a unitary rotation of the low-energy subspace $\mathcal{P}_0$ up to an error $O(N\epsilon^{m+1})$.

1.1 Applications of the SW method

The SW transformation finds application in many contemporary problems in quantum physics, where an economical description of the low-energy dynamics of the system must be extracted from a full Hamiltonian. While SW is named in honor of the authors of an important paper in condensed matter theory [3], where the celebrated Kondo Hamiltonian was shown to be obtained by such a transformation from the equally celebrated Anderson Hamiltonian, it is in fact not the earliest application of the technique. The concept of a most-economical rotation between subspaces has a several-centuries history in mathematics [4, 5]. Its direct descendent is the cosine-sine (CS) decomposition [6], which is very closely related to the definition of the exact SW transformation that we adopt here. The earliest application of the canonical transformation in quantum physics is in fact at least 15 years earlier than [3], in the famous transformation of Foldy and Wouthuysen [7]. The authors of [7] used the technique to derive the non-relativistic Schröedinger-Pauli wave equation, with relativistic corrections, from the Dirac equation. In this case, the canonical transformation is one that decouples the positive and negative energy solutions of the relativistic wave equation.

The applications of SW in modern times [8] are far too numerous even to allude to. The work of one of us uses SW routinely in many applications (see, e.g., Ref. [9]). Since part of our concern in the present work is a systematic development of a proper series expansion for the SW, we can mention that high-order terms of this series have been carefully and laboriously developed in some important works [10] and may be found recorded in recent books dealing with applications [11]. One can, however, find lengthy discussions of possible alternative approaches [12, 13]. It is widely acknowledged that SW is preferable to various other approaches, for example the Bloch expansion [14, 15], which, unlike SW, produces non-Hermitian effective Hamiltonians at sufficiently high order. SW is also superior to the self-consistent equation for the effective Hamiltonian arising from the diagrammatic self-energy technique [16, 17, 18].

It often occurs that the effective low-energy Hamiltonian has much higher level of complexity compared to the original high-energy Hamiltonian. This observation has lead to the idea of perturbation gadgets [18, 19, 20]. Suppose one starts from a target Hamiltonian H_{target} chosen for some interesting ground state properties. The target Hamiltonian may possibly contain many-body interactions and might not be very realistic. Perturbation gadgets formalism allows one to construct a simpler high-energy simulator Hamiltonian with only two-body interactions whose low-energy properties (such as the ground state energy) approximate the ones of H_{target}. For example, various perturbation gadgets have been constructed for target Hamiltonians with the topological quantum order [21, 22, 23]. The SW method provides a natural framework for constructing and analyzing perturbation gadgets [24]. In contrast to other methods, SW does not require the unphysical scaling of parameters in the simulator Hamiltonian required for convergence of the perturbative series [24]. This makes the SW method suitable for analysis of experimental implementations of perturbation gadgets with cold atoms in optical lattices, see [25, 26].

1.2 Comparison between SW and other perturbative expansions

In this section we briefly review some of the commonly used perturbative expansion techniques and argue that none of them can serve as a fully functional replacement of the SW method.

We begin by emphasizing that the effective Hamiltonian H_{eff} is only defined up to a unitary rotation of the low-energy subspace $\mathcal{P}_0$. Therefore one should expect that different versions of a degenerate perturbation theory produce different Taylor series for H_{eff}. In particular, the error up to which the series for H_{eff} truncated at some finite order reproduce the exact low-energy spectrum may depend on the method of computing H_{eff}. Different methods may also vary in the complexity of rules for computing the Taylor coefficients.

The most convenient and commonly used perturbative method is the Feynman-Dyson diagram technique [16, 17, 27]. It can be used whenever the unpertubed ground state obeys Wick's theorem. Unfortunately, the standard derivation of the Feynman-Dyson expansion (see, e.g., Ref. [17]) which relies on the adiabatic switching of a perturbation can only be applied to non-degenerate ground states. It was recently shown explicitly that the Gell-Mann and Low theorem used in the derivation of Feynman-Dyson series fails for degenerate ground states [28].

Exact quasi-adiabatic continuation [29, 30] provides an alternative path to defining H_{eff} via a unitary transformation starting from a full Hamiltonian. This method however requires a constant lower bound on the energy gap of a perturbed Hamiltonian which is typically very hard to check.

Traditional textbook treatment of a degenerate perturbation theory [31, 32, 33] is formulated in terms of perturbed and unperturbed resolvents

$$\tilde{G}(z) = (zI - H_0 - \epsilon V)^{-1} \quad \text{and} \quad G(z) = (zI - H_0)^{-1}.$$

An effective low-energy Hamiltonian can be obtained from $\tilde{G}(z)$ using the self-energy method [16, 17, 18]. To sketch the method, we shall adopt the standard notations by writing any operator O as a block matrix

$$O = \left[\begin{array}{cc} O_- & O_{-+} \\ O_{+-} & O_+ \end{array} \right] \tag{1.1}$$

where the two blocks correspond to the low-energy and the high-energy subspaces respectively. One can define an effective low-energy resolvent as $\tilde{G}_-(z)$, that is, the low-energy block of $\tilde{G}(z)$. Its importance comes from the fact that for sufficiently small ϵ eigenvalues of $H_0 + \epsilon V$ originating from the low-energy subspace coincide with the poles of $\tilde{G}_-(z)$, see [18]. The poles of $\tilde{G}_-(z)$ can be found using the Dyson equation [17]

$$\tilde{G}_-(z) = G_-(z) + \tilde{G}_-(z)\Sigma(z)G_-(z),$$

where

$$\Sigma(z) = \epsilon V_- + \sum_{n=0}^{\infty} \epsilon^{2+n}\, V_{-+}(G_+(z)V_+)^n G_+(z)V_{+-}$$

is the so-called self-energy operator acting on the low-energy subspace. The Dyson equation yields

$$\tilde{G}_-(z)^{-1} = G_-(z)^{-1} - \Sigma(z) = zI - (H_0)_- - \Sigma(z).$$

Hence z is an eigenvalue of $H_0 + \epsilon V$ originating from the low-energy subspace (the pole of $\tilde{G}_-(z)$) iff z is an eigenvalue of $(H_0)_- + \Sigma(z)$. In that sense one can regard $H_{\mathrm{eff}}(z) \equiv (H_0)_- + \Sigma(z)$ as a z-dependent effective Hamiltonian on the low-energy subspace. Although in many important cases the z-dependence of $H_{\mathrm{eff}}(z)$ can be neglected [18], there is no systematic way of getting rid of this dependence. This is the main disadvantage of the self-energy formalism compared with the SW method.

Another commonly used version of the degenerate perturbation theory is the expansion due to Bloch [14, 32, 15], see [20, 22] for some recent applications. The Bloch expansion is conceptually very similar to the SW method. It provides a systematic way of constructing an "effective Hamiltonian" acting on the low-energy subspace, but this Hamiltonian is generally not hermitian and as such it does not describe any physical theory. To make this point more clear let us recap the main steps of the Bloch expansion, see for instance [15, 20]. Let $\{|\psi_j\rangle\}_j$ be the eigenvectors $H_0 + \epsilon V$ originating from the low-energy subspace and $\{\lambda_j\}_j$ be the corresponding eigenvalues. Decompose

$$|\psi_j\rangle = |\alpha_j\rangle + |\alpha_j^\perp\rangle, \quad \text{where} \quad |\alpha_j\rangle \in \mathcal{P}_0 \quad \text{and} \quad |\alpha_j^\perp\rangle \in \mathcal{P}_0^\perp.$$

Define an operator $\mathcal{U}$ such that $\mathcal{U}\,|\alpha_j\rangle = |\psi_j\rangle$ and $\mathcal{U}\,|\psi\rangle = 0$ for all $\psi \in \mathcal{P}_0^\perp$. The operator $\mathcal{U}$ is analogous to the (inverse) SW transformation, although it is not unitary. Using the notations Eq. (1.1) one can write $\mathcal{U}$ as

$$\mathcal{U} = \left[\begin{array}{cc} I & 0 \\ \mathcal{U}_{+-} & 0 \end{array}\right].$$

It shows that $\mathcal{U}$ is a (non-hermitian) projector onto the perturbed low-energy subspace. Define the effective Hamiltonian acting on $\mathcal{P}_0$ as

$$H_{\mathrm{eff}} = P_0(H_0 + \epsilon V)\mathcal{U},$$

where P_0 is the projector onto $\mathcal{P}_0$. It follows that

$$H_{\mathrm{eff}}\,|\alpha_j\rangle = P_0(H_0 + \epsilon V)\,|\psi_j\rangle = \lambda_j\, P_0\,|\psi_j\rangle = \lambda_j\,|\alpha_j\rangle.$$

Thus one can regard H_{eff} as a counterpart of the effective Hamiltonian in the SW theory — it acts only on the unperturbed low-energy subspace and its spectrum reproduces eigenvalues of $H_0 + \epsilon V$ originating from the low-energy subspace. However, since $|\alpha_j\rangle$ do not constitute an orthonormal basis of $\mathcal{P}_0$, the operator H_{eff} is not hermitian, and thus it cannot be regarded as a physical Hamiltonian.

The advantage of the Bloch expansion is that the perturbative series for H_{eff} has somewhat simpler structure compared with the corresponding expansion in the SW method. Indeed, using the fact that $\mathcal{U}$ is a projector one easily gets

$$[H_0 + \epsilon V, \mathcal{U}]\mathcal{U} = 0. \tag{1.2}$$

Using the identities $P_0\mathcal{U} = P_0$ and $\mathcal{U}P_0 = \mathcal{U}$ one can rewrite Eq. (1.2) as

$$[H_0, \mathcal{U}] = -\epsilon[V, \mathcal{U}]\mathcal{U} = 0. \tag{1.3}$$

Expanding $\mathcal{U} = \sum_{n=0}^{\infty} \mathcal{U}_n \epsilon^n$ with $\mathcal{U}_0 = P_0$ and using Eq. (1.3) one can express $\mathcal{U}_n$ as a second-degree polynomial in $\mathcal{U}_1, \ldots, \mathcal{U}_{n-1}$ which provides a recursive rule for computing $\mathcal{U}_n$. This leads to a simple diagram technique for computing the Taylor coefficients of H_{eff}, see [15, 20] for details.

1.3 Organization of the paper

To be self-contained, the paper repeats some well-known results such as the low-order terms in the SW series. However we present these results in a very systematic and compact form that we believe might be useful for other workers.

Sections 2,3 provide an elementary introduction to the SW method for finite-dimensional Hilbert spaces. Section 2 summarizes the definition and basic facts concerning the direct rotation between linear subspaces. The direct rotation was originally introduced in the context of perturbation theory by Davis and Kahan in [4]. Although we hardly discover any new properties of the direct rotation, some of the basic facts such as the behavior of the direct rotation under tensor products (see Section 2.4) might not be very well-known.

Section 3 defines the SW transformation as the direct rotation from the low-energy subspace of a perturbed Hamiltonian $H_0 + \epsilon V$ to the low-energy subspace of H_0. This definition provides an elementary proof of additivity of H_{eff}. Namely, given a bipartite system AB with no interactions between A and B, the effective Hamiltonians $H_{\mathrm{eff}}[AB]$, $H_{\mathrm{eff}}[A]$, and $H_{\mathrm{eff}}[B]$ describing the joint system and the individual systems respectively are related as

$$H_{\mathrm{eff}}[AB] = H_{\mathrm{eff}}[A] \otimes I_B + I_A \otimes H_{\mathrm{eff}}[B].$$

Here I_A, I_B are the identity operators acting on the low-energy subspaces of A and B. We note that the above additivity does not hold on the entire Hilbert space as one could naively expect. In Section 3.2 we compute the Taylor series for the SW transformation and H_{eff}. Our presentation uses the formalism of superoperators to develop the series. It allows us to keep track of cancelations between different terms in a systematic way and obtain more compact expressions for the Taylor coefficients. A convenient diagram technique for computing H_{eff} is presented in Section 3.3. Convergence of the series is analyzed in Section 3.4. To the best of our knowledge, the approach taken in Sections 3.2,3.3,3.4 is new. Our main technical contributions are presented in Section 4 that specializes the SW method to weakly interacting spin systems.

2 Direct rotation between a pair of subspaces

The purpose of this section is to define a direct rotation between a pair of linear subspaces and derive its basic properties such as a multiplicativity under tensor products.

2.1 Rotation of one-dimensional subspaces

Let $\mathcal{H}$ be any finite-dimensional Hilbert space. For any normalized state $\psi \in \mathcal{H}$ define a reflection operator R_ψ that flips the sign of ψ and acts trivially on the orthogonal complement of ψ, that is,

$$R_\psi = I - 2|\psi\rangle\langle\psi|. \tag{2.1}$$

Given a pair of non-orthogonal states $\psi, \phi \in \mathcal{H}$ we would like to define a canonical unitary operator $U_{\psi\to\phi}$ mapping ψ to ϕ up to an overall phase. Let us first consider the double reflection operator $R_\phi R_\psi$. It rotates the two-dimensional subspace spanned by ψ and ϕ by 2θ, where $\theta \in [0, \pi/2)$ is the angle between ψ and ϕ. In addition, $R_\phi R_\psi$ acts as the identity in the orthogonal complement to ψ and ϕ. Thus we can choose the desired unitary operator mapping from ψ to ϕ as $U_{\psi\to\phi} = \sqrt{R_\phi R_\psi}$ assuming that the square root is well-defined.

Definition 2.1. *Let $\psi, \phi \in \mathcal{H}$ be any non-orthogonal states. Define a direct rotation from ψ to ϕ as a unitary operator*

$$U_{\psi\to\phi} = \sqrt{R_\phi R_\psi} \tag{2.2}$$

Here $\sqrt{z}$ is defined on a complex plane with a branch cut along the negative real axis such that $\sqrt{1} = 1$.

It is worth pointing out that any unitary operator is normal and thus the square root $\sqrt{R_\phi R_\psi}$ is well defined provided that $R_\phi R_\psi$ has no eigenvalues lying on the chosen branch cut of the $\sqrt{z}$ function. The following lemma shows that $U_{\psi\to\phi}$ is well defined and performs the desired transformation.

Lemma 2.1. *Let $\psi, \phi \in \mathcal{H}$ be any non-orthogonal states. Then the double reflection operator $R_\phi R_\psi$ has no eigenvalues on the negative real axis. Furthermore, fix the relative phase of ψ and ϕ such that $\langle\psi|\phi\rangle$ is real and positive. Then $U_{\psi\to\phi}|\psi\rangle = |\phi\rangle$.*

Proof. Since $U_{\psi\to\phi}$ acts as the identity on the subspace orthogonal to ψ and ϕ, it suffices to consider the case $\mathcal{H} = \mathbb{C}^2$. Without loss of generality $|\psi\rangle = |1\rangle$ and $|\phi\rangle = \sin(\theta)|0\rangle + \cos(\theta)|1\rangle$, where, by assumption, $0 \le \theta < \pi/2$. Using the definition Eq. (2.1) one gets

$$R_\psi = \sigma^z \quad \text{and} \quad R_\phi = \cos(2\theta)\,\sigma^z - \sin(2\theta)\,\sigma^x.$$

It yields

$$R_\phi R_\psi = \cos(2\theta)\, I + i\sin(2\theta)\,\sigma^y = \exp(2i\theta\sigma^y).$$

Since $0 \le 2\theta < \pi$, no eigenvalue of $R_\phi R_\psi$ lies on the negative real axis and thus

$$U_{\psi\to\phi} = \sqrt{R_\phi R_\psi} = \exp(i\theta\sigma^y)$$

is uniquely defined. We get $U_{\psi\to\phi}|1\rangle = \sin(\theta)|0\rangle + \cos(\theta)|1\rangle$, that is, $U_{\psi\to\phi}|\psi\rangle = |\phi\rangle$. □

Later on we shall need the following property of the direct rotation.

Corollary 2.1. *Let $\psi, \phi \in \mathcal{H}$ be any non-orthogonal states, $P = |\psi\rangle\langle\psi|$ and $P_0 = |\phi\rangle\langle\phi|$. The direct rotation from ψ to ϕ can be written as $U_{\psi\to\phi} = \exp(S)$ where S is an anti-hermitian operator with the following properties:*

- $PSP = P_0SP_0 = (I-P)S(I-P) = (I-P_0)S(I-P_0) = 0,$
- $\|S\| < \pi/2.$

Proof. Indeed, we can assume that $|\psi\rangle = |1\rangle$ and $|\phi\rangle = \sin(\theta)\,|0\rangle + \cos(\theta)\,|1\rangle$ for some $\theta \in [0, \pi/2)$. Choose $S = i\theta\sigma^y$ and $S = 0$ in the orthogonal complement to ψ and ϕ. By assumption, $\|S\| = |\theta| < \pi/2$. A simple algebra yields $\langle\psi|S|\psi\rangle = \langle\phi|S|\phi\rangle = 0$. Restricting all operators on the two-dimensional subspace spanned by ψ and ϕ one gets $(I-P)S(I-P) = \langle\psi^\perp|S|\psi^\perp\rangle$ and $(I-P_0)S(I-P_0) = \langle\phi^\perp|S|\phi^\perp\rangle$, where $|\psi^\perp\rangle = |0\rangle$ and $|\phi^\perp\rangle = \cos(\theta)\,|0\rangle - \sin(\theta)\,|1\rangle$. A simple algebra yields $\langle\psi^\perp|S|\psi^\perp\rangle = \langle\phi^\perp|S|\phi^\perp\rangle = 0$. □

2.2 Rotation of arbitrary subspaces

Let $\mathcal{P}, \mathcal{P}_0 \subseteq \mathcal{H}$ be a pair of linear subspaces of the same dimension and P, P_0 be the orthogonal projectors onto $\mathcal{P}, \mathcal{P}_0$. We would like to define a canonical unitary operator U mapping $\mathcal{P}$ to $\mathcal{P}_0$. By analogy with the non-orthogonality constraint used in the one-dimensional case we shall impose a constraint

$$\|P - P_0\| < 1. \tag{2.3}$$

The meaning of this constraint is clarified by the following simple fact.

Proposition 2.1. *Condition $\|P - P_0\| < 1$ holds iff no vector in $\mathcal{P}$ is orthogonal to $\mathcal{P}_0$ and vice verse. In particular, $\|P - P_0\| < 1$ implies that $\dim\mathcal{P} = \dim\mathcal{P}_0$.*

Proof. For any choice of the projectors P, P_0 the spectrum of $P - P_0$ lies on the interval $[-1, 1]$ which implies $\|P - P_0\| \le 1$. Suppose $\|P - P_0\| = 1$. Then there exists ψ such that $(P - P_0)\,|\psi\rangle = \pm|\psi\rangle$. This is possible only if $\langle\psi|P|\psi\rangle = 1$, $\langle\psi|P_0|\psi\rangle = 0$ or vice verse. Thus $\psi \in \mathcal{P}$ and $\psi \in \mathcal{P}_0^\perp$, or vice verse. Conversely, if such a vector ψ exists, then $(P - P_0)\,|\psi\rangle = \pm|\psi\rangle$, that is, $\|P - P_0\| = 1$. By the same token, if we assume that $\dim\mathcal{P} > \dim\mathcal{P}_0$ (or vice verse) there must exist a vector $\psi \in \mathcal{P}$ that is orthogonal to $\mathcal{P}_0$ (or vice verse), that is, $\|P - P_0\| = 1$. □

For any linear subspace $\mathcal{P}$ define a reflection operator $R_{\mathcal{P}}$ that flips the sign of all vectors in $\mathcal{P}$ and acts trivially on the orthogonal complement to $\mathcal{P}$, that is,

$$R_{\mathcal{P}} = 2P - I. \tag{2.4}$$

Following [4] let us define a direct rotation between a pair of subspaces as follows.

Definition 2.2. *Let $\sqrt{z}$ be the square-root function defined on a complex plane with a branch cut along the negative real axis and such that $\sqrt{1} = 1$. A unitary operator*

$$U = \sqrt{R_{\mathcal{P}_0} R_{\mathcal{P}}} \tag{2.5}$$

is called a direct rotation from $\mathcal{P}$ to $\mathcal{P}_0$.

Lemma 2.2. *Suppose $\|P - P_0\| < 1$. Then no eigenvalue of $R_{\mathcal{P}_0} R_{\mathcal{P}}$ lies on the negative real axis, so that U is uniquely defined by Eq. (2.5) and*

$$UPU^\dagger = P_0. \tag{2.6}$$

It is worth pointing out that the direct rotation U can also be defined as the 'minimal' rotation that maps $\mathcal{P}$ to $\mathcal{P}_0$. More specifically, among all unitary operators V satisfying $VPV^\dagger = P_0$ the direct rotation differs least from the identity in the Frobenius norm, see [4]. If, in addition, $\|P - P_0\| < \sqrt{3}/2$, the Frobenius norm can be replaced by the operator norm [4].

Proof of Lemma 2.2. It is well-known that any pair of projectors can be simultaneously block-diagonalized with blocks of size 2×2 and 1×1, and such that all 2×2 blocks are rank-one projectors, see Chapter 7.1 of [6]. It follows that all operators $P, P_0, R_{\mathcal{P}}, R_{\mathcal{P}_0}, U$ can be simultaneously block-diagonalized with blocks of size 2×2 and 1×1.

Let us first consider some 1×1 block. The restriction of P and P_0 on this block are scalars. The condition $\|P - P_0\| < 1$ implies that $P = P_0 = 0$ or $P = P_0 = 1$. Thus $R_{\mathcal{P}} = R_{\mathcal{P}_0} = \pm 1$. In both case $R_{\mathcal{P}_0} R_{\mathcal{P}} = 1$ and thus $U = 1$. Thus the identity $UPU^\dagger = P_0$ holds for any 1×1 block.

Let us now consider some 2×2 block. In this block one has $P = |\psi\rangle\langle\psi|$ and $P_0 = |\phi\rangle\langle\phi|$ for some one-qubit states $\psi, \phi \in \mathbb{C}^2$. The condition $\|P - P_0\| < 1$ implies that ψ and ϕ are non-orthogonal. In addition, the restriction of U onto the considered block coincides with the direct rotation $U_{\psi \to \phi}$, see Eq. (2.2). Therefore Lemma 2.1 implies that $UPU^\dagger = P_0$ in any 2×2 block. ☐

For the later use let us point out one extra property of the direct rotation which follows directly from the above proof and Corollary 2.1.

Corollary 2.2. *The direct rotation from $\mathcal{P}$ to $\mathcal{P}_0$ can be written as $U = \exp(S)$ where S is an anti-hermitian operator with the following properties:*

- $PSP = P_0 S P_0 = (I - P)S(I - P) = (I - P_0)S(I - P_0) = 0,$
- $\|S\| < \pi/2.$

Proof. Indeed, apply Corollary 2.1 to each block in the decomposition of P, P_0, and U. ☐

2.3 Generator of the direct rotation

The explicit formula Eq. (2.5) for the direct rotation U is not very useful if one needs to compute U perturbatively. In this section we describe an alternative definition of the direct rotation in terms of its generator, that is, an antihermitian operator S such that $U = \exp(S)$. We shall see later that the Taylor coefficients in the perturbative series for S can be computed using a simple inductive formula.

Lemma 2.3. *Suppose $\|P - P_0\| < 1$. Then there exists a unique anti-hermitian operator S with the following properties:*
(1) $\exp(S)P\exp(-S) = P_0$,
(2) S is block-off-diagonal with respect to P_0, that is,

$$P_0 S P_0 = 0 \quad \text{and} \quad (I - P_0)S(I - P_0) = 0. \tag{2.7}$$

(3) $\|S\| < \pi/2$.
The unitary operator $U = \exp(S)$ coincides with the direct rotation from $\mathcal{P}$ to $\mathcal{P}_0$.

Proof. We already know that there exists at least one operator S with the desired properties, see Corollary 2.2. Let us show that it is unique. Indeed, write S as

$$S = \begin{pmatrix} 0 & S_{1,2} \\ -S_{1,2}^\dagger & 0 \end{pmatrix}, \tag{2.8}$$

where the first and the second block correspond to the subspaces $\mathcal{P}_0$ and $\mathcal{P}_0^\perp$ respectively. Computing the exponent $\exp(S)$ yields

$$U = \exp(S) = \begin{pmatrix} U_{1,1} & U_{1,2} \\ -U_{1,2}^\dagger & U_{2,2} \end{pmatrix}$$

where

$$U_{1,1} = \cos(A), \quad A \equiv \sqrt{S_{1,2}S_{1,2}^\dagger} \quad \text{and} \quad U_{2,2} = \cos(B), \quad B = \sqrt{S_{1,2}^\dagger S_{1,2}}.$$

Note that $\|A\| = \|B\| = \|S\| < \pi/2$. Hence $U_{1,1}$ and $U_{2,2}$ are hermitian positive-definite operators,

$$U_{1,1} > 0 \quad \text{and} \quad U_{2,2} > 0. \tag{2.9}$$

Let $\tilde{S}$ be any anti-hermitian operator satisfying the three conditions of the lemma and let $\tilde{U} = \exp(\tilde{S})$. We have to prove that $\tilde{U} = U$ and $\tilde{S} = S$. Indeed, using the identity

$$(\tilde{U}U^\dagger)P_0(\tilde{U}U^\dagger)^\dagger = \tilde{U}P\tilde{U}^\dagger = P_0$$

we conclude that $\tilde{U}U^\dagger$ commutes with P_0. This is possible only if $\tilde{U}U^\dagger = L$ for some block-diagonal unitary L, that is,

$$L = \begin{pmatrix} L_1 & 0 \\ 0 & L_2 \end{pmatrix}, \quad L_1 L_1^\dagger = I, \quad L_2^\dagger L_2 = I.$$

It follows that $\tilde{U} = LU$, that is $\tilde{U}_{1,1} = L_1 U_{1,1}$ and $\tilde{U}_{2,2} = L_2 U_{2,2}$. Combining it with Eq. (2.9) we arrive at $L_1 = I$ and $L_2 = I$ as follows from the following proposition.

Proposition 2.2. *Let H be a positive operator and L be a unitary operator. Suppose that LH is also a positive operator. Then $L = I$.*

Proof. Indeed, consider the eigenvalue decomposition $L = \sum_\alpha e^{i\theta_\alpha} |\alpha\rangle\langle\alpha|$. Since $LH > 0$ one gets $\langle\alpha|LH|\alpha\rangle = e^{i\theta_\alpha}\langle\alpha|H|\alpha\rangle > 0$. Since $\langle\alpha|H|\alpha\rangle > 0$ we conclude that $e^{i\theta_\alpha} > 0$, that is, $e^{i\theta_\alpha} = 1$. Hence $L = I$. ☐

To summarize, we have shown that $\tilde{U} = U$. Since the matrix exponential function $\exp(M)$ is invertible on the subset of matrices satisfying $\|M\| < \pi/2$, we conclude that $\tilde{S} = S$. ☐

2.4 Weak multiplicativity of the direct rotation

Consider a bipartite system of Alice and Bob with a Hilbert space $\mathcal{H} = \mathcal{H}^A \otimes \mathcal{H}^B$. Let P^A, P_0^A be a pair of Alice's projectors acting on $\mathcal{H}^A$. Similarly, let P^B, P_0^B be a pair of Bob's projectors acting on $\mathcal{H}^B$. We shall assume that

$$\|P^A - P_0^A\| < 1 \quad \text{and} \quad \|P^B - P_0^B\| < 1 \tag{2.10}$$

such that one can define local direct rotations U^A and U^B,

$$U^A P^A (U^A)^\dagger = P_0^A \quad \text{and} \quad U^B P^B (U^B)^\dagger = P_0^B.$$

Consider also the global direct rotation U^{AB} mapping $P^A \otimes P^B$ to $P_0^A \otimes P_0^B$, that is,

$$U^{AB}(P^A \otimes P^B)(U^{AB})^\dagger = P_0^A \otimes P_0^B.$$

It is worth pointing out that in general $U^{AB} \ne U^A \otimes U^B$. Indeed, consider a special case when P^A and P^B project onto one-dimensional subspaces of Alice and Bob. Then clearly $P^A \otimes P^B$ is a rank-one projector. In this case U^{AB} is a rotation in some two-dimensional subspace of $\mathcal{H}$, see Section 2.1. On the other hand $U^A \otimes U^B$ is a tensor product of a rotation in some two-dimensional subspace of $\mathcal{H}^A$ and a rotation in some two-dimensional subspace of $\mathcal{H}^B$. Therefore $U^A \otimes U^B$ acts non-trivially on some four-dimensional subspace of $\mathcal{H}$ and hence $U^{AB} \ne U^A \otimes U^B$. This example shows that the direct rotation is not multiplicative under the tensor product. Nevertheless, it features a certain weaker form of multiplicativity which we derive in this section.

To start with, we need to check that the direct rotation U^{AB} is well-defined. It follows from the following proposition.

Proposition 2.3. *Suppose Alice's projectors P^A, P_0^A and Bob's projectors P^B, P_0^B satisfy non-orthogonality constraints Eq. (2.10). Then*

$$\|P^A \otimes P^B - P_0^A \otimes P_0^B\| < 1. \tag{2.11}$$

Proof. Let us assume that Eq. (2.11) is false. Then there exists a state $\psi \in \mathcal{H}$ such that $P^A \otimes P^B |\psi\rangle = 0$ and $P_0^A \otimes P_0^B |\psi\rangle = |\psi\rangle$ (or vice verse). Below we show that it leads to a contradiction. Indeed, the condition $\|P^A - P_0^A\| < 1$ implies that there exists $\alpha > 0$ such that $P^A - P_0^A \le (1-\alpha) I$. Multiplying this inequality on both sides by P^A we arrive at $P^A - P^A P_0^A P^A \le (1-\alpha) P^A$, that is, $P^A P_0^A P^A \ge \alpha P^A$. Similarly, there exists $\beta > 0$ such that $P^B P_0^B P^B \ge \beta P^B$. Thus

$$(P^A \otimes P^B)(P_0^A \otimes P_0^B)(P^A \otimes P^B) = (P^A P_0^A P^A) \otimes (P^B P_0^B P^B) \ge \alpha\beta P_0^A \otimes P_0^B. \tag{2.12}$$

Here we used the fact that a tensor product of positive semi-definite operators is a positive semi-definite operator. Computing the expectation value of Eq. (2.12) on ψ one gets $0 \ge \alpha\beta$ which is a contradiction. ☐

We conclude that the global direct rotation U^{AB} mapping $P^A \otimes P^B$ to $P_0^A \otimes P_0^B$ is well-defined. The relationship between the global and the local rotations which we shall call a *weak multiplicativity* is established by the following lemma.

Lemma 2.4 (Weak multiplicativity). *Let U^A, U^B, and U^{AB} be the direct rotations defined above. Then*

$$U^{AB}(P^A \otimes P^B) = (U^A \otimes U^B)(P^A \otimes P^B). \tag{2.13}$$

Proof. Let us perform the simultaneous block-diagonalization of P^A, P_0^A and P^B, P_0^B with blocks of size 2×2 and 1×1, as in the proof of Lemma 2.2. Recall that each 2×2 block is a rank-one projector. Hence it suffices to check Eq. (2.13) only for the case when $\mathcal{H}^A = \mathcal{H}^B = \mathbb{C}^2$ and rank-one projectors P^A, P^B, P_0^A, P_0^B. Choose normalized states ψ^A, ψ^B, ψ_0^A, ψ_0^B in the range of the above projectors, and fix their relative phase such that $\langle \psi^A | \psi_0^A \rangle > 0$ and $\langle \psi^B | \psi_0^B \rangle > 0$. Lemma 2.1 implies that $U^A |\psi^A\rangle = |\psi_0^A\rangle$ and $U^B |\psi^B\rangle = |\psi_0^B\rangle$. However, since $\langle \psi^A \otimes \psi^B | \psi_0^A \otimes \psi_0^B \rangle > 0$, Lemma 2.1 also implies that $U^{AB} |\psi^A \otimes \psi^B\rangle = |\psi_0^A \otimes \psi_0^B\rangle$. This we have an identity $U^{AB}(P^A \otimes P^B) = (U^A \otimes U^B)(P^A \otimes P^B)$ in each tensor product of 2×2 blocks. Similar arguments hold if one or both blocks have size 1×1. ☐

3 Effective low-energy Hamiltonian

3.1 Schrieffer-Wolff transformation

Let $\mathcal{H}$ be a finite-dimensional Hilbert space and H_0 be a hermitian operator on $\mathcal{H}$. We shall refer to H_0 as an *unperturbed Hamiltonian.* Let $\mathcal{I}_0 \subseteq \mathbb{R}$ be any interval containing one or several eigenvalues of H_0 and let $\mathcal{P}_0 \subseteq \mathcal{H}$ be the subspace spanned by all eigenvectors of H_0 with eigenvalue lying in $\mathcal{I}_0$. We shall say that H_0 has a *spectral gap* Δ iff for any pair of eigenvalues λ, η such that $\lambda \in \mathcal{I}_0$ and $\eta \notin \mathcal{I}_0$ one has $|\lambda - \eta| \ge \Delta$. In other words, the eigenvalues of H_0 lying in $\mathcal{I}_0$ must be separated from the rest of the spectrum by a gap at least Δ.

Consider now a perturbed Hamiltonian $H = H_0 + \epsilon V$, where the perturbation V is an arbitrary hermitian operator on $\mathcal{H}$. Let $\mathcal{I} \subseteq \mathbb{R}$ be the interval obtained from $\mathcal{I}_0$ by adding margins of thickness $\Delta/2$ on the left and on the right of $\mathcal{I}_0$. Let $\mathcal{P} \subseteq \mathcal{H}$ be the subspace spanned by all eigenvectors of

H with eigenvalue lying in $\mathcal{I}$. In this section we shall only consider sufficiently weak perturbations that do no close the gap separating the interval $\mathcal{I}_0$ from the rest of the spectrum. Specifically, we shall assume that $|\epsilon| \le \epsilon_c$, where

$$\epsilon_c = \frac{\Delta}{2\|V\|}. \tag{3.1}$$

Since the perturbation shifts any eigenvalue at most by $\|\epsilon V\|$, we conclude that the eigenvalues of H lying in $\mathcal{I}$ are separated from the rest of the spectrum of H by a positive gap as long as $|\epsilon| < \epsilon_c$. In particular, it implies that $\mathcal{P}_0$ and $\mathcal{P}$ have the same dimension. Let P_0 and P be the orthogonal projectors onto $\mathcal{P}_0$ and $\mathcal{P}$. Introduce also projectors $Q_0 = I - P_0$ and $Q = I - P$.

Lemma 3.1. *Suppose ϵ is real and $|\epsilon| < \epsilon_c$. Then $\|P_0 - P\| \le 2\|\epsilon V\|/\Delta < 1$.*

Proof. Let $T = P - P_0$. A simple algebra shows that T^2 is block-diagonal with respect to P_0 and Q_0, that is $P_0 T^2 Q_0 = 0$ and $Q_0 T^2 P_0 = 0$. The remaining diagonal blocks of T^2 are $P_0 T^2 P_0 = P_0 Q P_0$ and $Q_0 T^2 Q_0 = Q_0 P Q_0$. Since T is hermitian, we have $\|T\| = \sqrt{\|T^2\|}$ and thus

$$\|T\| = \max\left(\sqrt{\|P_0 Q P_0\|}, \sqrt{\|Q_0 P Q_0\|}\right) = \max\left(\|P_0 Q\|, \|Q_0 P\|\right).$$

Let us assume that $\|T\| = \|P_0 Q\|$ (the case $\|T\| = \|P Q_0\|$ is dealt with analogously[2]). Define auxiliary operators $A = P_0 H_0 P_0$, $B = QHQ$, and $X = P_0 Q$. Then one has

$$AX - XB = P_0(H_0 - H)Q = -\epsilon P_0 V Q \equiv Y. \tag{3.2}$$

The equation $AX - XB = Y$ is known as the Sylvester equation. In particular, it is known that $\|X\| \le \delta^{-1}\|Y\|$ whenever spectrums of A and B can be separated by an annulus of width δ in the complex plane, see for instance, Theorem VII.2.11 in [6]. In our case the spectrums of A and B considered as operators on P_0 and Q respectively are separated by an annulus of width $\Delta/2$ whenever $|\epsilon| < \epsilon_c$. Thus we arrive at

$$\|X\| \le (2/\Delta)\,\|Y\| \le (2/\Delta)\,\|\epsilon V\| < 1$$

as long as $|\epsilon| < \epsilon_c$. □

Lemma 3.1 implies that the direct rotation U from $\mathcal{P}$ to $\mathcal{P}_0$ is well-defined as long as $|\epsilon| < \epsilon_c$. By definition, it satisfies $UPU^\dagger = P_0$ and $UQU^\dagger = Q_0$. In addition, since the perturbed Hamiltonian $H = H_0 + \epsilon V$ is block-diagonal with respect to P and Q, we conclude that the transformed Hamiltonian $UHU^\dagger$ is block-diagonal with respect to P_0 and Q_0. In almost all applications of perturbation theory the interval $\mathcal{I}_0$ includes only the smallest eigenvalue of H_0 or all sufficiently small eigenvalues. By a slight abuse of notations we shall adopt the standard terminology and refer to $\mathcal{P}_0$ as the *low-energy* subspace of H_0. However, one should keep in mind that all results of this section remain valid for an arbitrary choice of the interval $\mathcal{I}_0$.

Definition 3.1. *The direct rotation U from $\mathcal{P}$ to $\mathcal{P}_0$ is called the Schrieffer-Wolff (SW) transformation for the unperturbed Hamiltonian H_0, perturbation ϵV, and the low-energy subspace $\mathcal{P}_0$. The operator $H_{\text{eff}} = P_0 U (H_0 + \epsilon V) U^\dagger P_0$ is called an effective low-energy Hamiltonian.*

---

[2] It is worth mentioning that $\|P - P_0\| = \|P_0 Q\| = \|Q_0 P\|$ for any projectors P, P_0 satisfying $\|P - P_0\| < 1$. These identities can be easily proved using the simultaneous block-diagonalized form of P and P_0.

3.2 Derivation of the perturbative series

Let U be the Schrieffer-Wolff transformation constructed for some unperturbed Hamiltonan H_0, a perturbation ϵV, and the low-energy subspace $\mathcal{P}_0$. In this section we always assume that $|\epsilon| < \epsilon_c$, so U is well-defined, see Lemma 3.1. In most of applications the explicit formula Eq. (2.5) for the SW transformation cannot be used directly because the low-energy subspace $\mathcal{P}$ of the perturbed Hamiltonian $H_0 + \epsilon V$ is unknown. In this section we explain how one can compute the transformation U and the effective low-energy Hamiltonian H_{eff} perturbatively. Truncating the series for H_{eff} at some finite order one obtains an effective low-energy theory describing properties of the perturbed system. Throughout this section all series are treated as formal series. Their convergence will be proved later in Section 3.4.

We begin by introducing some notations. The space of linear operators acting on $\mathcal{H}$ will be denoted $\mathbb{L}(\mathcal{H})$. A linear map $\mathcal{O} : \mathbb{L}(\mathcal{H}) \to \mathbb{L}(\mathcal{H})$ will be referred to as a *superoperator*. We shall often use superoperators

$$\mathcal{O}(X) = P_0 X Q_0 + Q_0 X P_0 \quad \text{and} \quad \mathcal{D}(X) = P_0 X P_0 + Q_0 X Q_0.$$

We shall say that an operator X is *block-off-diagonal* iff $\mathcal{O}(X) = X$. An operator X is called *block-diagonal* iff $\mathcal{D}(X) = X$. Decompose the perturbation V as $V = V_{\text{d}} + V_{\text{od}}$, where

$$V_{\text{d}} = \mathcal{D}(V) \quad \text{and} \quad V_{\text{od}} = \mathcal{O}(V)$$

are block-diagonal and block-off-diagonal parts of V. Given any operator $Y \in \mathbb{L}(\mathcal{H})$ define a superoperator $\hat{Y}$ describing the adjoint action of Y, that is, $\hat{Y}(X) = [Y, X]$.

Recall that the SW transformation can be uniquely represented as $U = \exp(S)$ where S is an anti-hermitian generator which is block-off-diagonal and $\|S\| < \pi/2$, see Lemma 2.3, whereas the transformed Hamiltonian $e^S(H_0 + \epsilon V)e^{-S}$ is block-diagonal. Combining these conditions would yield Taylor series for S, which, in turn, yields Taylor series for H_{eff}. We begin by rewriting the transformed Hamiltonian as

$$\exp(\hat{S})(H_0 + \epsilon V) = \cosh(\hat{S})(H_0 + \epsilon V_{\text{d}}) + \sinh(\hat{S})(\epsilon V_{\text{od}}) + \sinh(\hat{S})(H_0 + \epsilon V_{\text{d}}) + \cosh(\hat{S})(\epsilon V_{\text{od}}). \quad (3.3)$$

Taking into account that S is block-off-diagonal, we conclude that the first and the second terms in the righthand side of Eq. (3.3) are block-diagonal, while the third and the fourth terms are block-off-diagonal. In order for the transformed Hamiltonian to be block-diagonal, S must obey

$$\sinh(\hat{S})(H_0 + \epsilon V_{\text{d}}) + \cosh(\hat{S})(\epsilon V_{\text{od}}) = 0.$$

Since our goal is to derive formal Taylor series, S can be regarded as an infinitesimally small operator. In this case the superoperator $\cosh(\hat{S})$ is invertible and thus the above condition can be rewritten as

$$\tanh(\hat{S})(H_0 + \epsilon V_{\text{d}}) + \epsilon V_{\text{od}} = 0. \quad (3.4)$$

Now we can rewrite the transformed Hamiltonian as

$$\begin{aligned}\exp(\hat{S})(H_0+\epsilon V) &= \cosh(\hat{S})(H_0+\epsilon V_{\mathrm{d}})+\sinh(\hat{S})(\epsilon V_{\mathrm{od}})\\ &= H_0+\epsilon V_{\mathrm{d}}+(\cosh(\hat{S})-1)(H_0+\epsilon V_{\mathrm{d}})+\sinh(\hat{S})(\epsilon V_{\mathrm{od}})\\ &= H_0+\epsilon V_{\mathrm{d}}+\frac{(\cosh(\hat{S})-1)}{\tanh(\hat{S})}\tanh(\hat{S})(H_0+\epsilon V_{\mathrm{d}})+\sinh(\hat{S})(\epsilon V_{\mathrm{od}}).\end{aligned}$$

Note that $(\cosh(\hat{S})-1)/\tanh(\hat{S})$ is well defined for infinitesimally small S by its Taylor series. Using Eq. (3.4) we arrive at

$$\exp(\hat{S})(H_0+\epsilon V)=H_0+\epsilon V_{\mathrm{d}}+F(\hat{S})(\epsilon V_{\mathrm{od}}),$$

where

$$F(x)=\sinh(x)-\frac{\cosh(x)-1}{\tanh(x)}.$$

A simple algebra shows that $F(x)=\tanh(x/2)$, so we finally get

$$\exp(\hat{S})(H_0+\epsilon V)=H_0+\epsilon V_{\mathrm{d}}+\tanh(\hat{S}/2)(\epsilon V_{\mathrm{od}}). \tag{3.5}$$

In order to solve Eq. (3.4) for S let us introduce some more notations. Let $\{|i\rangle\}$ be an orthonormal eigenbasis of H_0 such that $H_0|i\rangle=E_i|i\rangle$ for all i. We shall use notation $i\in\mathcal{I}_0$ as a shorthand for $E_i\in\mathcal{I}_0$. Define a superoperator

$$\mathcal{L}(X)=\sum_{i,j}\frac{\langle i|\mathcal{O}(X)|j\rangle}{E_i-E_j}|i\rangle\langle j|. \tag{3.6}$$

Note that $\langle i|\mathcal{O}(X)|j\rangle=0$ whenever $i,j\in\mathcal{I}_0$ or $i,j\notin\mathcal{I}_0$. Let us agree that the sum in Eq. (3.6) includes only the terms with $i\in\mathcal{I}_0$, $j\notin\mathcal{I}_0$ or vice verse. In this case the energy denominator can be bounded as $|E_i-E_j|\ge\Delta$. One can easily check that

$$\mathcal{L}([H_0,X])=[H_0,\mathcal{L}(X)]=\mathcal{O}(X) \tag{3.7}$$

for any operator $X\in\mathbb{L}(\mathcal{H})$. It is worth mentioning that $\mathcal{L}$ maps hermitian operators to anti-hermitian operators and vice verse.

Treating S as an infinitesimally small operator we can rewrite Eq. (3.4) as

$$\hat{S}(H_0+\epsilon V_{\mathrm{d}})+\hat{S}\coth(\hat{S})(\epsilon V_{\mathrm{od}})=0.$$

Using Eq. (3.7) and the fact that S is block-off-diagonal one gets

$$S=\mathcal{L}\,\hat{S}(\epsilon V_{\mathrm{d}})+\mathcal{L}\,\hat{S}\coth(\hat{S})(\epsilon V_{\mathrm{od}}). \tag{3.8}$$

We can solve Eq. (3.8) in terms of Taylor series,

$$S=\sum_{n=1}^{\infty}S_n\,\epsilon^n,\quad S_n^\dagger=-S_n. \tag{3.9}$$

Let us also agree that $S_0 = 0$. We shall need the Taylor series

$$x \coth(x) = \sum_{n=0}^{\infty} a_{2n} x^{2n}, \quad a_m = \frac{2^m B_m}{m!}, \tag{3.10}$$

where B_m are the Bernoulli numbers. Then we have

$$\begin{aligned} S_1 &= \mathcal{L}(V_{\mathrm{od}}), \\ S_2 &= -\mathcal{L}\hat{V}_{\mathrm{d}}(S_1), \\ S_n &= -\mathcal{L}\hat{V}_{\mathrm{d}}(S_{n-1}) + \sum_{j\ge 1} a_{2j}\mathcal{L}\,\hat{S}^{2j}(V_{\mathrm{od}})_{n-1} \qquad \text{for } n \ge 3. \end{aligned} \tag{3.11}$$

Here we used a shorthand

$$\hat{S}^k(V_{\mathrm{od}})_m = \sum_{\substack{n_1,\ldots,n_k\ge 1\\ n_1+\ldots+n_k=m}} \hat{S}_{n_1}\cdots\hat{S}_{n_k}(V_{\mathrm{od}}). \tag{3.12}$$

Note that the righthand side of Eq. (3.11) depends only on $S_1,\ldots,S_{n-1}$. Hence Eq. (3.11) provides an inductive rule for computing the Taylor coefficients S_n. Projecting Eq. (3.5) onto the low-energy subspace one gets

$$H_{\mathrm{eff}} = H_0 P_0 + \epsilon P_0 V P_0 + \sum_{n=2}^{\infty} \epsilon^n H_{\mathrm{eff},n}, \quad H_{\mathrm{eff},n} = \sum_{j\ge 1} b_{2j-1} P_0\,\hat{S}^{2j-1}(V_{\mathrm{od}})_{n-1} P_0. \tag{3.13}$$

Here b_{2j-1} are the Taylor coefficients of the function $\tanh(x/2)$. More explicitly,

$$\tanh(x/2) = \sum_{n=1}^{\infty} b_{2n-1} x^{2n-1}, \quad b_{2n-1} = \frac{2(2^{2n}-1)B_{2n}}{(2n)!}. \tag{3.14}$$

Note that $H_{\mathrm{eff},n}$ depends only upon $S_1,\ldots,S_{n-1}$. To illustrate the method let us compute the Taylor coefficients $H_{\mathrm{eff},n}$ for small values of n (a systematic way of computing $H_{\mathrm{eff},n}$ in terms of diagrams is described in the next section). From Eq. (3.11) one easily finds

$$\begin{aligned} S_3 &= -\mathcal{L}\hat{V}_{\mathrm{d}}(S_2) + a_2\mathcal{L}\,\hat{S}_1^2(V_{\mathrm{od}}), \\ S_4 &= -\mathcal{L}\hat{V}_{\mathrm{d}}(S_3) + a_2\mathcal{L}\,(\hat{S}_1\hat{S}_2 + \hat{S}_2\hat{S}_1)(V_{\mathrm{od}}). \end{aligned}$$

From Eq. (3.13) one gets

$$H_{\mathrm{eff},2} = b_1 P_0 \hat{S}_1(V_{\mathrm{od}}) P_0, \tag{3.15}$$

$$H_{\mathrm{eff},3} = b_1 P_0 \hat{S}_2(V_{\mathrm{od}}) P_0, \tag{3.16}$$

$$H_{\mathrm{eff},4} = b_1 P_0 \hat{S}_3(V_{\mathrm{od}}) P_0 + b_3 P_0 \hat{S}_1^3(V_{\mathrm{od}}) P_0, \tag{3.17}$$

$$H_{\mathrm{eff},5} = b_1 P_0 \hat{S}_4(V_{\mathrm{od}}) P_0 + b_3 P_0 (\hat{S}_2\hat{S}_1^2 + \hat{S}_1\hat{S}_2\hat{S}_1 + \hat{S}_1^2\hat{S}_2)(V_{\mathrm{od}}) P_0. \tag{3.18}$$

a_0	a_2	a_4	a_6
1	1/3	−1/45	2/945

b_1	b_3	b_5	b_7
1/2	−1/24	1/240	−17/40320

Figure 1: The value of the Taylor coefficients a_{2n} and b_{2n-1} for small n.

Let us obtain explicit formulas for $H_{\mathrm{eff},3}$ and $H_{\mathrm{eff},4}$ that include only S_1. Using the identity $\hat{S}_2(V_{\mathrm{od}}) = -\hat{V}_{\mathrm{od}}(S_2)$ we get

$$H_{\mathrm{eff},3} = b_1 P_0 \hat{V}_{\mathrm{od}} \mathcal{L} \hat{V}_{\mathrm{d}}(S_1) P_0 \tag{3.19}$$

and

$$S_3 = (\mathcal{L}\hat{V}_{\mathrm{d}})^2(S_1) + a_2 \mathcal{L}\hat{S}_1^2(V_{\mathrm{od}}).$$

Substituting S_3 into the expression for $H_{\mathrm{eff},4}$ and using the identity $\hat{S}_3(V_{\mathrm{od}}) = -\hat{V}_{\mathrm{od}}(S_3)$ one gets

$$H_{\mathrm{eff},4} = P_0 \left[-b_1 \hat{V}_{\mathrm{od}} (\mathcal{L}\hat{V}_d)^2(S_1) - b_1 a_2 \hat{V}_{\mathrm{od}} \mathcal{L} \hat{S}_1^2(V_{\mathrm{od}}) + b_3 \hat{S}_1^3(V_{\mathrm{od}}) \right] P_0. \tag{3.20}$$

The explicit values of the Taylor coefficients a_{2n} and b_{2n-1} are listed in Table 1. The formula for $H_{\mathrm{eff},4}$ can be slightly simplified in the special case when $\mathcal{I}_0$ contains a single eigenvalue of H_0, that is, the restriction of H_0 onto P_0 is proportional to the identity operator. In this special case one can use an identity

$$P_0[\mathcal{L}(X), \mathcal{O}(Y)]P_0 = -P_0[\mathcal{O}(X), \mathcal{L}(Y)]P_0 \tag{3.21}$$

which holds for any operators X, Y. One can easily check Eq. (3.21) by computing matrix elements $\langle i| \cdot |j\rangle$ of both sides for $i, j \in \mathcal{I}_0$. Using Eq. (3.21) and explicit values of a's and b's one can rewrite $H_{\mathrm{eff},4}$ as

$$H_{\mathrm{eff},4} = P_0 \left[\frac{1}{8} \hat{S}_1^3(V_{\mathrm{od}}) - \frac{1}{2} \hat{V}_{\mathrm{od}} (\mathcal{L}\hat{V}_d)^2(S_1) \right] P_0. \tag{3.22}$$

To summarize, the Taylor series for the effective low-energy Hamiltonian can be written as

$$\begin{aligned} H_{\mathrm{eff}} &= H_0 P_0 + \epsilon P_0 V P_0 + \frac{\epsilon^2}{2} P_0 \hat{S}_1(V_{\mathrm{od}}) P_0 + \frac{\epsilon^3}{2} P_0 \hat{V}_{\mathrm{od}} \mathcal{L} \hat{V}_{\mathrm{d}}(S_1) P_0 \\ &\quad - \epsilon^4 P_0 \left[\frac{1}{2} \hat{V}_{\mathrm{od}} (\mathcal{L}\hat{V}_{\mathrm{d}})^2(S_1) + \frac{1}{6} \hat{V}_{\mathrm{od}} \mathcal{L} \hat{S}_1^2(V_{\mathrm{od}}) + \frac{1}{24} \hat{S}_1^3(V_{\mathrm{od}}) \right] P_0 + O(\epsilon^5), \end{aligned} \tag{3.23}$$

with the simplification Eq. (3.22) in the case when the restriction of H_0 onto the low-energy subspace is proportional to the identity operator.

3.3 Schrieffer-Wolff diagram technique

In this section we develop a diagram technique for the effective low-energy Hamiltonian. By analogy with the Feynman-Dyson diagram technique, we shall represent the n-th order Taylor coefficient $H_{\mathrm{eff},n}$ as a weighted sum over certain class of admissible diagrams. In our case n-th order diagrams will be trees with n nodes obeying certain restrictions imposed on the node degrees. Any such diagram represents a linear operator acting on the low-energy subspace $\mathcal{P}_0$. Loosely speaking, every edge of the tree stands for a commutator, while every node of the tree stands for $V_{\rm d}$ or $V_{\rm od}$. The weight associated with a diagram depends only on node degrees and can be easily expressed in terms of the Bernoulli numbers.

Let us now proceed with formal definitions. Let T be a connected tree with n nodes. Each node $u \in T$ has at most one parent node and zero or more children nodes. The children of any node are ordered in some fixed way. We shall denote children of a node u as $u(1), \ldots, u(k)$, where k is the number of children (NOC) of u. Nodes having no children are called *leaves*. There is a unique *root* node which has no parent node.

For any node $u \in T$ we shall define a linear operator O_u acting on the full Hilbert space $\mathcal{H}$. The definition is inductive, so we shall start from the leaves and move up towards the root.

- If u is a leaf then $O_u = S_1 \equiv \mathcal{L}(V_{\rm od})$.
- If $u \ne$ root has $k \ge 2$ children and k is even then $O_u = \mathcal{L}\, \hat{O}_{u(1)} \cdots \hat{O}_{u(k)}(V_{\rm od})$.
- If $u \ne$ root has exactly one child then $O_u = -\mathcal{L}\hat{V}_{\rm d}(O_{u(1)})$.
- If $u =$ root has k children with odd k then $O_u = P_0\, \hat{O}_{u(1)} \cdots \hat{O}_{u(k)}(V_{\rm od})P_0$.
- In all remaining cases $O_u = 0$.

Recall that $\hat{O} \equiv {\rm ad}_O$ describes the adjoint action of O. Define an operator $O(T)$ associated with T as $O(T) = O_r$, where r is the root of T. It is clear from the above definition that $O(T)$ is an operator acting on the low-energy subspace $\mathcal{P}_0$ and $O(T)$ has degree n in the perturbation V. Furthermore, $O(T) = 0$ unless the root of T has odd NOC and every node different from the root with more than one child has even NOC.

Definition 3.2. *A connected tree T is called admissible iff*

- *The root of T has odd NOC,*
- *Every node different from the root has either even NOC or NOC=1.*

A complete list of admissible trees (modulo isomorphisms) with $n = 3, 4, 5, 6$ nodes is shown on Fig. 2. To illustrate the definition of operators $O(T)$ let us consider fourth-order diagrams. Let T_1, T_2, T_3 be the admissible trees with four nodes shown on Fig. 2 (listed from the left to the right). Then one has

$$\begin{aligned}
O(T_1) &= -P_0\hat{V}_{\rm od}(\mathcal{L}\hat{V}_{\rm d})^2(S_1)P_0, \\
O(T_2) &= -P_0\hat{V}_{\rm od}\mathcal{L}\hat{S}_1^2(V_{\rm od})P_0, \\
O(T_3) &= P_0\hat{S}_1^3(V_{\rm od})P_0. \qquad (3.24)
\end{aligned}$$

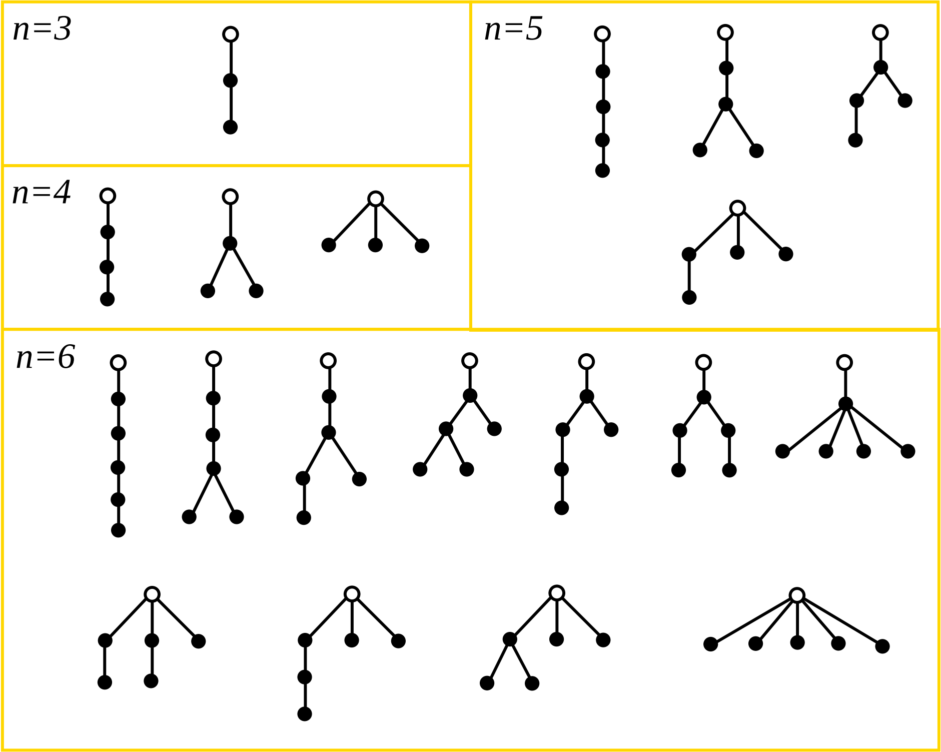

Figure 2: A set of admissible trees $\mathcal{T}(n)$ with $n = 3, 4, 5, 6$ nodes. Only one representative for each class of isomorphic trees is shown. The total number of admissible trees (counting isomorphic trees) is $|\mathcal{T}(n)| = 1, 3, 7, 20$ for $n = 3, 4, 5, 6$ respectively,

For any tree T define a weight

$$w(T) = \prod_{u \in T} w(u), \tag{3.25}$$

where the product is over all nodes of T and

$$w(u) = \begin{cases} 1 & \text{if} \quad u \neq \text{root has exactly one child}, \\ a_k & \text{if} \quad u \neq \text{root has } k \text{ children for some even } k, \\ b_k & \text{if} \quad u = \text{root has } k \text{ children for some odd } k, \\ 0 & \quad\;\; \text{otherwise}. \end{cases} \tag{3.26}$$

Recall that

$$a_{2n} = \frac{2^{2n} B_{2n}}{(2n)!} \quad \text{and} \quad b_{2n-1} = \frac{2(2^{2n}-1)B_{2n}}{(2n)!},$$

where B_{2n} are the Bernoulli numbers, see also Table 1. The main result of this section is the following lemma.

Lemma 3.2. *The Taylor series for $H_{\rm eff}$ can be written as*

$$H_{\rm eff} = H_0 P_0 + \epsilon P_0 V P_0 + \sum_{n=2}^{\infty} \sum_{T \in \mathcal{T}(n)} \epsilon^n \, w(T) \, O(T), \tag{3.27}$$

where $\mathcal{T}(n)$ is the set of all admissible trees with n nodes.

Proof. Let us first develop a diagram technique for the generator S. Let T be any connected tree. For any node $u \in T$ we shall define a linear operator O'_u acting on the full Hilbert space $\mathcal{H}$. The definition is inductive, so we shall start from the leaves and move up towards the root.

- If u is a leaf then $O'_u = S_1 \equiv \mathcal{L}(V_{\rm od})$.
- If u has exactly one child then $O'_u = -\mathcal{L}\hat{V}_{\rm d}(O'_{u(1)})$.
- If u has k children and k is even then $O'_u = \mathcal{L}\, \hat{O}'_{u(1)} \cdots \hat{O}'_{u(k)}(V_{\rm od})$.
- In all remaining cases $O'_u = 0$.

Define an operator $O'(T)$ associated with T as $O'(T) = O'_r$, where r is the root of T. It is clear from the above definition that $O'(T)$ is a block-off-diagonal operator and $O'(T)$ has degree n in the perturbation V. Furthermore, $O'(T) = 0$ unless all nodes of T with more than one child have even NOC.

Definition 3.3. *A tree T is called S-admissible iff any node of T with more than one child has even number of children.*

Define a *weight* of a tree T as

$$w'(T) = \prod_{u \in T} w'(u), \tag{3.28}$$

where the product is over all nodes of T and

$$w'(u) = \begin{cases} 1 & \text{if} \quad u \text{ has exactly one child,} \\ a_k & \text{if} \quad u \text{ has } k \text{ children for some even } k, \\ 0 & \quad\;\; \text{otherwise.} \end{cases} \tag{3.29}$$

Lemma 3.3. *The generator of the SW transformation can be written as*

$$S = \sum_{n=1}^{\infty} \sum_{T \in \mathcal{T}'(n)} \epsilon^n \, w'(T) \, O'(T). \tag{3.30}$$

where $\mathcal{T}'(n)$ is the set of all S-admissible trees with n nodes.

Proof. We can use induction in n to show that S_n is the sum of $w'(T)O'(T)$ over all S-admissible trees with n nodes. The base of induction is $n = 1$ in which case there is only one S-admissible tree T (a single node) and $O'(T) = S_1$. To prove the induction hypothesis for general n we can use Eq. (3.11) and Eq. (3.12). Repeatedly expanding $\hat{S}^{2j}$ in Eq. (3.11) one gets a sum over S-admissible trees, where the operators O'_u correspond to S_{n_i} encountered in the course of the expansion. ☐

Substituting the Taylor series Eq. (3.30) into Eq. (3.13) one arrives at Eq. (3.27). ☐

3.4 Convergence radius

In this section we analyze convergence of the formal series $S = \sum_{j=1}^{\infty} S_j \, \epsilon^j$ and $H_{\text{eff}} = \sum_{j=1}^{\infty} H_{\text{eff},j} \, \epsilon^j$.

Lemma 3.4. *The series for S and H_{eff} converge absolutely in the disk $|\epsilon| < \rho_c$ where*

$$\rho_c = \frac{\epsilon_c}{8\left(1 + \frac{2|\mathcal{I}_0|}{\pi\Delta}\right)}.$$

Here $\epsilon_c = \Delta/(2\|V\|)$ and $|\mathcal{I}_0|$ is the width of the interval $\mathcal{I}_0$.

Proof. Define projectors $Q_0 = I - P_0$ and $P = I - P$. Simple algebra shows that

$$R_{P_0} R_P = I + Z, \quad \text{where} \quad Z = -2(P_0 Q + Q_0 P).$$

For any $\rho > 0$ define a disk $D(\rho) = \{\epsilon \in \mathbb{C} \, : \, |\epsilon| < \rho\}$. It is well-known that $P = P(\epsilon)$ has analytic continuation to $D(\epsilon_c)$. Indeed, choose a contour γ in the complex plane as the boundary of the $(\Delta/2)$-neighborhood of the interval $\mathcal{I}_0$, see Fig. 3. Then any eigenvalue of H_0 has distance at least

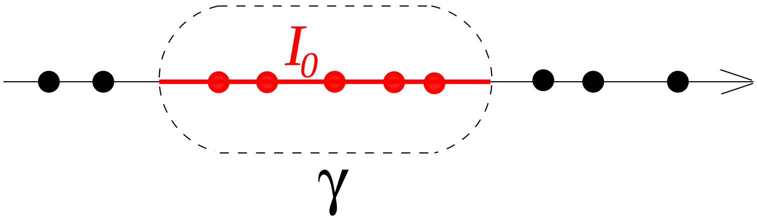

Figure 3: The contour γ (dashed black curve) encircling the interval $\mathcal{I}_0$ (bold red). Eigenvalues of H_0 are indicates by solid dots.

$\Delta/2$ from γ and $\|(zI - H_0)^{-1}\| \le 2/\Delta$ for all $z \in \gamma$. It implies that for any $z \in \gamma$ the resolvent $(zI - H)^{-1}$ is analytic in $D(\epsilon_c)$. Thus we can define

$$P = \frac{1}{2\pi i} \int_\gamma dz (zI - H_0 - \epsilon V)^{-1} \tag{3.31}$$

and the Taylor series $P = P_0 + \sum_{j=1}^\infty P_j\, \epsilon^j$ converges absolutely in the disk $D(\epsilon_c)$. Furthermore, one can easily check that P is a projector, $P^2 = P$, for all $\epsilon \in D(\epsilon_c)$. Note however that P is not hermitian for complex ϵ and thus one may have $\|P\| > 1$ (clearly, $\|P\| \ge 1$ for any non-zero projector P since $\langle \psi|P|\psi\rangle = 1$ for some state ψ).

Using the standard perturbative expansion of the resolvent in Eq. (3.31) one gets a Taylor series

$$P = P_0 + \sum_{j=1}^\infty P_j\, \epsilon^j, \quad P_j = \frac{1}{2\pi i} \int_\gamma dz (zI - H_0)^{-1} \left(V (zI - H_0)^{-1} \right)^j.$$

Noting that the contour γ has length $|\gamma| = \pi\Delta + 2|\mathcal{I}_0|$, we can bound the norm of P_j for $j \ge 1$ as

$$\|P_j\, \epsilon^j\| \le \left(1 + \frac{2|\mathcal{I}_0|}{\pi\Delta}\right) \cdot \left(\frac{2\|\epsilon V\|}{\Delta}\right)^j = \left(1 + \frac{2|\mathcal{I}_0|}{\pi\Delta}\right) \cdot (|\epsilon|/\epsilon_c)^j.$$

It follows that

$$\|P_0 Q\| = \|P_0 - P_0 P\| \le \sum_{j=1}^\infty \|P_0 P_j\, \epsilon^j\| \le \sum_{j=1}^\infty \|P_j\, \epsilon^j\| \le \left(1 + \frac{2|\mathcal{I}_0|}{\pi\Delta}\right) \cdot \frac{|\epsilon|}{\epsilon_c - |\epsilon|} < \frac{1}{4}$$

where the last inequality holds for $|\epsilon| < \rho_c$. The same bound applies to $\|Q_0 P\|$. It follows that Z is analytic in the disk $D(\rho_c)$ and $\|Z\| \le 2(\|P_0 Q\| + \|Q_0 P\|) < 1$. Thus the series for $S = \log(U) = (1/2)\log(I + Z)$ converges absolutely in the disk $|\epsilon| < \rho_c$. $\square$

3.5 Additivity of the effective Hamiltonian

Consider a bipartite system of Alice and Bob with a Hilbert space $\mathcal{H} = \mathcal{H}^A \otimes \mathcal{H}^B$. Assume that both H_0 and V can be represented as a sum of local terms acting non-trivially only on Alice or Bob,

$$H_0 = H_0^A \otimes I^B + I^A \otimes H_0^B \quad \text{and} \quad V = V^A \otimes I^B + I^A \otimes V^B.$$

In this section we choose the low-energy subspaces $\mathcal{P}_0^A \subseteq \mathcal{H}^A$ and $\mathcal{P}_0^B \subseteq \mathcal{H}^B$ as the ground state subspaces of Alice's and Bob's Hamiltonians H_0^A and H_0^B respectively. Let $\mathcal{P}^A \subseteq \mathcal{H}^A$ and $\mathcal{P}^B \subseteq \mathcal{H}^B$ be the ground state subspaces of the perturbed Alice's and Bob's Hamiltonians $H_0^A + \epsilon V^A$ and $H_0^B + \epsilon V^B$ respectively. Let U^A and U^B be the local SW-transformations on Alice's and Bob's subsystems such that

$$U^A P^A (U^A)^\dagger = P_0^A \quad \text{and} \quad U^B P^B (U^B)^\dagger = P_0^B. \tag{3.32}$$

Applying the SW-transformation independently to Alice's and Bob's subsystems one obtains a pair of effective Hamiltonians

$$H_{\text{eff}}^A = P_0^A U^A (H_0^A + \epsilon V^A)(U^A)^\dagger P_0^A \quad \text{and} \quad H_{\text{eff}}^B = P_0^B U^B (H_0^B + \epsilon V^B)(U^B)^\dagger P_0^B.$$

Since there are no interactions between the two subsystems, the combined low-energy effective Hamiltonian can be defined as $H_{\text{eff}}^A \otimes I^B + I^A \otimes H_{\text{eff}}^B$.

On the other hand, one can consider the global SW-transformation U^{AB} acting the full Hilbert space $\mathcal{H} = \mathcal{H}^A \otimes \mathcal{H}^B$ and mapping the ground subspace of $H_0 + \epsilon V$ to the ground subspace of H_0 such that

$$U^{AB}(P^A \otimes P^B)(U^{AB})^\dagger = P_0^A \otimes P_0^B. \tag{3.33}$$

It generates the effective low-energy Hamiltonian

$$H_{\text{eff}}^{AB} = (P_0^A \otimes P_0^B) U^{AB} (H_0 + \epsilon V)(U^{AB})^\dagger (P_0^A \otimes P_0^B).$$

As was pointed out in Section 2.4, in general $U^{AB} \neq U^A \otimes U^B$. Nevertheless it turns out that the effective low-energy Hamiltonians obtained 'globally' and 'locally' are the same. We shall refer to this property as *additivity* of the effective Hamiltonian. The additivity will play the key role in Section 4 in which we prove that the effective low-energy Hamiltonians describing weakly interacting spin systems inherit locality properties of the original Hamiltonian (the so called linked cluster property).

Lemma 3.5 (Additivity). *Let H_{eff}^A, H_{eff}^B, and H_{eff}^{AB} be the low-energy effective Hamiltonians defined above. Then*

$$H_{\text{eff}}^{AB} = H_{\text{eff}}^A \otimes I^B + I^A \otimes H_{\text{eff}}^B. \tag{3.34}$$

Proof. The additivity of H_{eff} follows directly from the weak multiplicativity of the direct rotation, see Lemma 2.4. Indeed, using Eq. (2.13), Eq. (3.32), and Eq. (3.33) one gets

$$(P_0^A \otimes P_0^B) U^{AB} = (P_0^A \otimes P_0^B)(U^A \otimes U^B) \quad \text{and} \quad (U^{AB})^\dagger (P_0^A \otimes P_0^B) = (U^A \otimes U^B)^\dagger (P_0^A \otimes P_0^B)$$

which implies Eq. (3.34). □

It is worth mentioning that additivity of H_{eff}^{AB} does not apply to individual diagrams in its perturbative expansion, see Section 3.3. The simplest counter-example is a system of two qutrits (spins $S = 1$), that is, $\mathcal{H}^A = \mathcal{H}^B = \mathbb{C}^3$. Choosing a basis of $\mathbb{C}^3$ as $\{|0\rangle, |1\rangle, |2\rangle\}$, we can define Hamiltonians $H_0^A = H_0^B = |2\rangle\langle 2|$ such that $\mathcal{P}_0^A = \mathcal{P}_0^B = \mathbb{C}^2$ is spanned by $|0\rangle$ and $|1\rangle$. Choosing V^A

and V^B as generic (random) 3×3 hermitian matrices we computed numerically individual diagrams $O(T_1), O(T_2), O(T_3)$ that contribute to the fourth-order effective Hamiltonian $H^{AB}_{eff,4}$, see Eqs. (3.24). Note that $O(T_i)$ are two-qubit operators acting on $\mathcal{P}_0^A \otimes \mathcal{P}_0^B = \mathbb{C}^2 \otimes \mathbb{C}^2$. We observed numerically that $\langle 0,0|O(T_i)|1,1\rangle \neq 0$ for all $i = 1,2,3$. It shows that individual diagrams $O(T_i)$ contain interactions between A and B.

4 Schrieffer-Wolff theory for quantum many-body systems

In this section we specialize the SW method to many-body systems such as spin chains and spin lattices. The Hilbert space describing these systems has a a tensor product structure $\mathcal{H} = \bigotimes_{a=1}^N \mathcal{H}_a$, where $\mathcal{H}_a$ is a local Hilbert space describing the a-th spin and N is the total number of spins. We shall assume that the unperturbed Hamiltonian H_0 is a sum of single-spin operators, so that its low-energy subspace $\mathcal{P}_0$ by itself has a tensor product structure, $\mathcal{P}_0 = \bigotimes_{a=1}^N \mathcal{P}_{0,a}$, where $\mathcal{P}_{0,a} \subseteq \mathcal{H}_a$ is the low-energy subspace of the a-th spin. A perturbation V will be chosen as a sum of two-spin interactions such that each spin can interact only with $O(1)$ other spins. Our assumption on H_0 and V are formally stated in Section 4.1.

The main technical difficulty with applying general techniques of Section 3 to many-body systems such as spin lattices is that the norm $\|\epsilon V\|$ is typically a macroscopic quantity proportional to the total number of spins N. On the other hand, the spectral gap Δ of the unperturbed Hamiltonian H_0 does not grow with N. It means that $\|\epsilon V\| \sim N \gg \Delta$ and thus the SW transformation is not well-defined, see Lemma 3.1. By the same token, the Taylor series for the SW generator S and the effective Hamiltonian H_{eff} derived in Section 3.2 could be divergent. We shall get around this difficulty by considering the Taylor series $H_{\mathrm{eff}} = \sum_{q \geq 0} H_{\mathrm{eff},q}\, \epsilon^q$ truncated at some fixed order n,

$$H_{\mathrm{eff}}^{\langle n\rangle} = P_0 H_0 + \epsilon P_0 V P_0 + \sum_{q=2}^{n} H_{\mathrm{eff},q}\, \epsilon^q. \tag{4.1}$$

Note that $H_{\mathrm{eff}}^{\langle n\rangle}$ is a polynomial in ϵ of finite degree, so it is well defined even if the series for H_{eff} is divergent.

Since the low-energy subspace $\mathcal{P}_0$ has a tensor product structure, one can ask whether the truncated Hamiltonian $H_{\mathrm{eff}}^{\langle n\rangle}$ can be written as a sum of local interactions. In Section 4.3 we use additivity of H_{eff} to show that a Taylor coefficient $H_{\mathrm{eff},q}$ includes only interactions among subsets of spins that are spanned by *connected* clusters of q edges in the interaction graph, see Theorem 2. It demonstrates that the SW transformation maps a high-energy Hamiltonian with local interactions to an effective low-energy Hamiltonian with (approximately) local interactions.

Our main result is the following theorem.

Theorem 1. *There exists a constant threshold $\epsilon_c > 0$ depending only on n, Δ, and the maximum degree of the interaction graph such that for all $|\epsilon| < \epsilon_c$ the ground state energy of $H_{\mathrm{eff}}^{\langle n\rangle}$ approximates the ground state energy of $H_0 + \epsilon V$ with an error at most $\delta_n = O(N|\epsilon|^{n+1})$.*

We begin by proving the theorem for the special case of so-called block-diagonal perturbations, see Section 4.2. These are perturbations composed of local interactions preserving the low-energy subspace $\mathcal{P}_0$. For block-diagonal perturbations the SW transformation is trivial, that is, $S = 0$, see Section 3.2. It follows that $H_{\mathrm{eff}} = P_0 H_0 + \epsilon P_0 V P_0$. Clearly, H_{eff} can reproduce ground state properties of the exact Hamiltonian $H_0 + \epsilon V$ only if at least one ground state of $H_0 + \epsilon V$ belongs to the low-energy subspace $\mathcal{P}_0$. We prove that this is indeed the case if $|\epsilon| < \epsilon_c'$ for some constant $\epsilon_c' > 0$ that depends only on the gap Δ, maximum degree of the interaction graph, and the strength of interactions in V, see Lemma 4.1.

The role of the SW transformation is to map generic perturbations to block-diagonal perturbations. Unfortunately, the SW transformation cannot be used directly since the transformed truncated Hamiltonian $U(H_0+\epsilon V)U^\dagger$ becomes local only when restricted to $\mathcal{P}_0$, while Lemma 4.1 requires locality on the entire Hilbert space. In addition, the Taylor coefficients S_p of the SW generator are highly non-local operators which complicates an analysis of the error obtained by truncating the series at some finite order. We resolve this problem by employing an auxiliary perturbative expansion due to Datta et al [2] which we refer to as a *local Schrieffer-Wolff* transformation, see Section 4.4. It defines an effective low-energy Hamiltonian

$$H_{\mathrm{eff,loc}} = P_0\, e^T (H_0 + \epsilon V) e^{-T} P_0$$

for some unitary transformation e^T. This transformation is constructed such that the transformed Hamiltonian $e^T(H_0+\epsilon V)e^{-T}$ is block-diagonal, that is, it can be written as a sum of (approximately) local interactions preserving $\mathcal{P}_0$. Here the locality of interactions holds on the full Hilbert space which allows us to apply Lemma 4.1. In Section 4.4 we prove an analogue of Theorem 1 for the n-th order effective Hamiltonian constructed using the local SW method. The proof uses some of techniques developed by Datta et al [2] to bound the error resulting from truncating the series for the generator T.

Finally, we construct a unitary transformation e^K acting on the low-energy subspace P_0 that maps the effective low-energy Hamiltonians obtained using the standard and the local SW methods to each other, that is, $H_{\mathrm{eff}} = e^K H_{\mathrm{eff,loc}} e^{-K}$, see Section 4.5. The relationship between low-energy theories obtained using the standard and the local SW methods is illustrated on Fig. 4. We use weak multiplicativity of the SW transformation proved in Section 2.4 to show that the perturbative expansion of K contains only linked clusters. This linked cluster property of K allows us to bound the error resulting from truncating the series for K at the n-th order by $O(N|\epsilon|^{n+1})$. Combining the two errors we obtain the desired bound on δ_n in Theorem 1.

4.1 The unperturbed Hamiltonian and the perturbation

Let Λ be a lattice or a graph with N sites such that each site $u \in \Lambda$ is occupied by a finite-dimensional particle (spin) with a local Hilbert space $\mathcal{H}_u$. Accordingly, the full Hilbert space is

$$\mathcal{H} = \bigotimes_{u\in\Lambda} \mathcal{H}_u.$$

We will choose the unperturbed Hamiltonian H_0 as a sum of single-spin operators,

$$H_0 = \sum_{u\in\Lambda} H_{0,u}, \tag{4.2}$$

where $H_{0,u}$ acts non-trivially only on a spin u. By performing an overall energy shift we can always assume that each term $H_{0,u}$ is a positive semi-definite operator and the ground state energy of $H_{0,u}$ is zero. Let $\mathcal{P}_{0,u} \subseteq \mathcal{H}_u$ be the ground subspace of a spin u and $P_{0,u}$ be the tensor product of the projector onto $\mathcal{P}_{0,u}$ and the identity operator on all other spins. Then the ground subspace of the entire Hamiltonian H_0 is

$$\mathcal{P}_0 = \bigotimes_{u\in\Lambda} \mathcal{P}_{0,u}$$

and the projector onto $\mathcal{P}_0$ can be represented as

$$P_0 = \prod_{u\in\Lambda} P_{0,u}.$$

Let $Q_0 = I - P_0$ be the projector onto $\mathcal{P}_0^\perp$ and $Q_{0,u} = I - P_{0,u}$. We shall assume that each term $H_{0,u}$ has a spectral gap at least Δ above the ground state. Thus the full Hamiltonian H_0 also has a spectral gap at least Δ. In general, the maximal norm of the local terms $\|H_{0,u}\|$ is a parameter independent of Δ. However, for the sake of simplicity we shall assume that

$$\|H_{0,u}\| = O(\Delta) \quad \text{for all } u \in \Lambda.$$

It is worth mentioning that if we allow each spin to have two or more distinct levels in the low-energy subspace $\mathcal{P}_{0,u}$, the full Hamiltonian might not have a spectral gap between the subspaces $\mathcal{P}_0$ and $\mathcal{P}_0^\perp$. Consider as an example the case when each spin has 3 basis states $|0\rangle, |1\rangle, |2\rangle$ which have energy 0, $\delta > 0$, and $\Delta \gg \delta$ respectively such that the low-energy subspace $\mathcal{P}_{0,u}$ is spanned by the states $|0\rangle$ and $|1\rangle$. Then the state $|1^{\otimes N}\rangle \in \mathcal{P}_0$ has energy $N\delta$ while the state $|2, 0^{\otimes(N-1)}\rangle \in \mathcal{P}_0^\perp$ has energy Δ. Thus for any constant δ and Δ the spectral gap between $\mathcal{P}_0$ and $\mathcal{P}_0^\perp$ closes if $N \geq \Delta\delta^{-1}$.

We will choose the perturbation V as a sum of two-spin interactions between nearest neighbor sites,

$$V = \sum_{(u,v)\in\mathcal{E}} V_{u,v}.$$

Here $\mathcal{E}$ is the set of edges of the underlying lattice (which could be an arbitrary graph) and $V_{u,v}$ is an arbitrary hermitian operator acting on a pair of sites u, v. To describe the effective low-energy theory we will have to consider k-*local* perturbations, that is, Hamiltonians with at most k-spin interactions. A k-local perturbation V can be written as

$$V = \sum_{A\subseteq\Lambda} V_A, \qquad V_A = 0 \text{ unless } |A| \leq k.$$

Here V_A is an arbitrary hermitian operator acting on a subset of spins A. Define a *strength* of the perturbation as

$$J = \max_{u\in \Lambda} \sum_{A\subseteq \Lambda\, :\, A\ni u} \|V_A\|. \tag{4.3}$$

The strength of the perturbation provides an upper bound on the combined norm of all interactions affecting any selected spin. If Λ is a regular lattice in a space of bounded dimension then J coincides up to a constant factor with the maximum norm of interactions, $J \sim \max_A \|V_A\|$. We will always assume that J and Δ are constants independent of N. Let us say that a perturbation $V = \sum_{A\subseteq\Lambda} V_A$ is *block-diagonal* iff V_A preserves the low-energy subspace $\mathcal{P}_0$, or equivalently, $[V_A, P_0] = 0$.

4.2 Block-diagonal perturbations

Recall that the goal of the SW transformation U is to transform the perturbed Hamiltonian $H_0 + \epsilon V$ into a block-diagonal form such that the transformed Hamiltonian $U(H_0 + \epsilon V)U^\dagger$ preserves the low-energy subspace $\mathcal{P}_0$. In this section we analyze the special case when the perturbed Hamiltonian $H_0 + \epsilon V$ is already block-diagonal, so that $U = I$. In this case the effective low-energy Hamiltonian is simply $H_{\mathrm{eff}} = P_0(H_0 + \epsilon V)P_0$. Since we assumed that $H_0P_0 = 0$, one has $H_{\mathrm{eff}} = \epsilon P_0VP_0$. A natural question is whether the ground state energy of H_{eff} coincides with the ground state energy of $H_0 + \epsilon V$. Clearly, this happens iff at least one ground state of $H_0 + \epsilon V$ belongs to the subspace $\mathcal{P}_0$. In this section we prove that this is indeed the case provided that the strength of the perturbation ϵV is below certain constant threshold depending only on Δ and k. Intuitively it follows from the fact that exciting any subset of w spins increases the energy of the term H_0 by at least $w\Delta$, while the energy of the term ϵV can go down at most by $2w|\epsilon|J$. Hence exciting spins can only increase the energy provided that $|\epsilon| < \epsilon_c \sim \Delta/J$. Unfortunately this simple argument does not tell anything about states that contain superpositions of different excited subsets with different w, and one may expect that exciting subsets of spins "in a superposition" can help to reduce the overall energy. We analyze this general situation in the following lemma (to simplify notations we include the factor ϵ into the definition of V).

Lemma 4.1. *Let $V = \sum_{A\subseteq\Lambda} V_A$ be a k-local perturbation with strength J. Suppose that each term V_A is block-diagonal, that is, V_A preserves the subspace $\mathcal{P}_0$. Assume also that $2^{k+2}J < \Delta$. Then the subspace $\mathcal{P}_0$ contains at least one ground state of $H_0 + V$.*

Let us emphasize that the lemma does not tell anything about the spectral gap of the perturbed Hamiltonian $H_0 + V$ separating the subspaces $\mathcal{P}_0$ and $\mathcal{P}_0^\perp$. We believe that this gap can be closed by perturbations with a strength of order $1/N$.

Proof. Let us assume that $H_0 + V$ has a ground state $|\psi\rangle \in \mathcal{P}_0^\perp$. We will show that this assumption leads to a contradiction. Indeed, we can represent such a ground state $|\psi\rangle$ as a sum over $2^N - 1$ configurations of excited spins,

$$|\psi\rangle = \sum_{x\in\{0,1\}^N} |\psi_x\rangle, \tag{4.4}$$

where x is a binary string of length N such that $x_u = 1$ indicates that a spin u is excited ($P_{0,u}\,|\psi_x\rangle = 0$) and $x_u = 0$ indicates that a spin u is not excited ($P_{0,u}\,|\psi_x\rangle = |\psi_x\rangle$). More formally,

$$|\psi_x\rangle = R(x)\,|\psi\rangle, \quad \text{where} \quad R(x) = \prod_{u\in\Lambda}((1-x_u)P_{0,u} + x_u Q_{0,u}).$$

We note that $|\psi_x\rangle$ may be a highly entangled state. Since we assumed $|\psi\rangle \in \mathcal{P}^\perp$, the configuration with no excited spins does not appear in $|\psi\rangle$, that is,

$$|\psi_{0^N}\rangle = 0.$$

Let us choose a configuration $x^* \in \{0,1\}^N$ with the largest amplitude

$$\alpha_x = \langle\psi_x|\psi_x\rangle,$$

that is,

$$\alpha_{x^*} \ge \alpha_x \quad \text{for all } x. \tag{4.5}$$

The key idea is to transform $|\psi\rangle$ to a new state η (which is generally mixed) by "annihilating" all excitations in $|\psi_{x^*}\rangle$ while leaving all other components $|\psi_x\rangle$, $x \ne x^*$, untouched. We will show that for sufficiently small strength of V the energy of η is smaller than the energy of $|\psi\rangle$ thus arriving at a contradiction.

For any spin $u \in \Lambda$ choose an arbitrary ground state $|\omega_u\rangle \in \mathcal{P}_{0,u}$. Define a trace preserving completely positive (TPCP) map $\mathcal{E}_u$ that erases the state of the spin u and replaces it by the chosen ground state $|\omega_u\rangle$. More formally, for any (mixed) state τ describing the entire system one has

$$\mathcal{E}_u(\tau) = |\omega_u\rangle\langle\omega_u| \otimes \operatorname{Tr}_u(\tau).$$

Note that $\mathcal{E}_u(\tau)$ may be mixed even if τ is a pure state. The map $\mathcal{E}_u$ can be regarded as an "annihilation superoperator". Obviously, annihilation superoperators on different spins commute with each other. Let ρ be a state obtained from $|\psi_{x^*}\rangle$ by applying the annihilation superoperator to every excited spin, that is,

$$\rho = \left(\prod_{u\,:\,x^*_u=1} \mathcal{E}_u\right)(|\psi_{x^*}\rangle\langle\psi_{x^*}|).$$

Clearly, $\mathcal{E}_u$ reduces the energy of the term $H_{0,u}$ at least by $\Delta\alpha_{x^*}$ for any excited spin u. Thus if we denote the number of excited spins (the Hamming weight of the string x^*) by w then

$$\operatorname{Tr}(\rho\, H_0) \le \langle\psi_{x^*}|H_0|\psi_{x^*}\rangle - w\Delta\,\alpha_{x^*}. \tag{4.6}$$

Now consider a state obtained from $|\psi\rangle$ be removing the largest-amplitude term,

$$|\psi_{\mathrm{else}}\rangle = \sum_{x\ne x^*} |\psi_x\rangle.$$

Denote

$$\eta = \rho + |\psi_{\mathrm{else}}\rangle\langle\psi_{\mathrm{else}}|. \tag{4.7}$$

Since $\mathcal{E}_u$ are trace preserving maps, we have $\mathrm{Tr}\,\rho = \langle\psi_{x^*}|\psi_{x^*}\rangle$ and thus $\mathrm{Tr}\,\eta = \langle\psi|\psi\rangle = 1$. Let us show that for sufficiently small strength of V the energy of η is smaller than the energy of $|\psi\rangle$, thus getting a contradiction. Indeed, since H_0 cannot change a configuration of excited spins we have

$$\mathrm{Tr}\,(\eta H_0) - \langle\psi|H_0|\psi\rangle = \mathrm{Tr}\,(\rho\, H_0) - \langle\psi_{x^*}|H_0|\psi_{x^*}\rangle \le -w\Delta\,\alpha_{x^*}, \tag{4.8}$$

see Eq. (4.6). It remains to bound the contribution to the energy coming from the perturbation V. Simple algebra leads to

$$\mathrm{Tr}\,(\eta V) - \langle\psi|V|\psi\rangle = \sum_{A\subseteq\Lambda} \mathrm{Tr}\,(\rho V_A) - \langle\psi_{x^*}|V_A|\psi_{x^*}\rangle - 2\mathrm{Re}(\langle\psi_{x^*}|V_A|\psi_{else}\rangle). \tag{4.9}$$

Note that the states ρ and $|\psi_{x^*}\rangle$ have the same reduced density matrices on any subset $A\subseteq\Lambda$ that contains no excited spins, that is, $x^*_u = 0$ for all $u\in A$. It follows from the fact that annihilation superoperators applied outside A cannot change the reduced state of A. Therefore

$$\mathrm{Tr}\,(\rho V_A) - \langle\psi_{x^*}|V_A|\psi_{x^*}\rangle = 0 \quad \text{if } x^*_u = 0 \text{ for all } u\in A. \tag{4.10}$$

Taking into account that any interaction V_A is block-diagonal, the operator V_A can change a configuration of excited spins only if at least one spin in A is already excited. It means that

$$\langle\psi_{x^*}|V_A|\psi_{else}\rangle = 0 \quad \text{if } x^*_u = 0 \text{ for all } u\in A. \tag{4.11}$$

Using Eq. (4.10) we get a bound

$$\left|\sum_{A\subseteq\Lambda} \mathrm{Tr}\,(\rho V_A) - \langle\psi_{x^*}|V_A|\psi_{x^*}\rangle\right| \le \sum_{u\,:\,x^*_u=1}\sum_{A\ni u} |\mathrm{Tr}\,(\rho V_A) - \langle\psi_{x^*}|V_A|\psi_{x^*}\rangle| \le 2w\alpha_{x^*}J. \tag{4.12}$$

It bounds the contribution to the energy from the first and the second terms in Eq. (4.9). Now let us bound the contribution from the last term in Eq. (4.9). Using Eq. (4.11) we get

$$\begin{aligned}\left|\sum_{A\subseteq\Lambda} 2\mathrm{Re}(\langle\psi_{x^*}|V_A|\psi_{else}\rangle)\right| &\le \sum_{u\,:\,x^*_u=1}\sum_{A\ni u}\sum_{x\ne x^*} 2|\langle\psi_{x^*}|V_A|\psi_x\rangle| \\ &\le \sum_{u\,:\,x^*_u=1}\sum_{A\ni u} 2^{k+1}\|V_A\|\sqrt{\alpha_{x^*}\alpha_x} \\ &\le 2\cdot 2^k w\alpha_{x^*}J. \end{aligned} \tag{4.13}$$

Here the first line follows from Eq. (4.11) and definition of $|\psi_{else}\rangle$. The second line follows from the Cauchy-Schwarz inequality and the fact that V_A acts non-trivially on at most k spins, so the number of possible transitions $x^* \to x$ is upper bounded by 2^k. The third line follows from the maximality condition Eq. (4.5). Combining bounds Eq. (4.12,4.13) we arrive at

$$|\mathrm{Tr}\,(\eta V) - \langle\psi|V|\psi\rangle| \le 2^{k+2} w \alpha_{x^*} J. \tag{4.14}$$

Combining it with Eq. (4.8) we finally get

$$\mathrm{Tr}\,(\eta H) - \langle\psi|H|\psi\rangle \le (-\Delta + 2^{k+2}J) w \alpha_{x^*}. \tag{4.15}$$

Since by assumption x^* contains at least one excitation, we have $w > 0$. It means that the energy of η is strictly smaller than the one of $|\psi\rangle$ if $2^{k+2}J < \Delta$. However this is impossible since $|\psi\rangle$ is a ground state. Thus our assumption $|\psi\rangle \in \mathcal{P}^\perp$ leads to a contradiction. □

Lemma 4.1 can be easily generalized to the case when V contains interactions among arbitrarily large number of spins, but the magnitude of k-spin interactions decays exponentially with k.

Corollary 4.1. *Consider a Hamiltonian $V = \sum_{a=1}^n V_a$ such that V_a is a $k(a)$-local perturbation with strength $J(a)$. Suppose that all interactions in each perturbation V_a are block-diagonal. Assume also that*

$$\sum_{a=1}^n 2^{k(a)+2}\, J(a) < \Delta. \tag{4.16}$$

Then the subspace $\mathcal{P}_0$ contains at least one ground state of $H_0 + V$.

4.3 Linked cluster theorem

Let $\epsilon_{u,v}$ be formal variables associated with the edges of the lattice $(u,v) \in \mathcal{E}$. Consider a perturbation

$$V = \sum_{(u,v)\in\mathcal{E}} \epsilon_{u,v} V_{u,v}.$$

Using the perturbative expansion described in Section 3.2 one can represent the effective low-energy Hamiltonian H_{eff} acting on $\mathcal{P}_0$ as a formal operator-valued multivariate series in variables $\epsilon_{u,v}$. Clearly any Taylor coefficient $H_{\mathrm{eff},n}$ is a homogeneous multivariate polynomial in $\epsilon_{u,v}$ of degree n. One can uniquely represent $H_{\mathrm{eff},n}$ as a sum of monomials

$$K \prod_{(u,v)\in C} \epsilon_{u,v}^{m_{u,v}}, \quad m_{u,v} \ge 1, \quad \sum_{(u,v)\in C} m_{u,v} = n,$$

where K is some operator acting on $\mathcal{P}_0$ and $C \subseteq \mathcal{E}$ is a subset of edges of the lattice. We shall refer to C as the *support* of the above monomial. Thus we have

$$H_{\mathrm{eff},n} = \sum_{C\subseteq\mathcal{E}} K_{n,C}, \tag{4.17}$$

where $K_{n,C}$ is defined as the sum of all monomials in H_{eff} that have support C and degree n. Given any set of edges $C \subseteq \mathcal{E}$ let $\Lambda(C) \subseteq \Lambda$ be the corresponding set of sites, such that $u \in \Lambda(C)$ iff C contains an edge incident to u.

Let us point out that the only purpose of introducing the variables $\epsilon_{u,v}$ is to define the operators $K_{n,C}$ and the decomposition Eq. (4.17). Once this decomposition is defined, we can set $\epsilon_{u,v} = \epsilon$ for all edges. Also note that we do not make any assumptions about convergence of H_{eff} considered as a multivariate series[3] since we only consider some fixed order n. The main result of this section is the following theorem.

Theorem 2 (linked cluster theorem). *The operator $K_{n,C}$ acts only on the subset of spins $\Lambda(C)$. In addition, $K_{n,C} = 0$ unless C is a connected subset of edges and $|C| \le n$.*

Thus the n-th order effective Hamiltonian includes only interactions among "linked clusters" of spins of size at most n. However let us point out that the theorem does not say that $K_{n,C}$ acts non-trivially on *all* spins in $\Lambda(C)$.

Proof. Choose any subset of edges $C \subseteq \mathcal{E}$ and set $\epsilon_{u,v} = 0$ for all $(u,v) \notin C$. Partition the lattice as $\Lambda = AB$ where $A = \Lambda(C)$ and B is the complement of A. Then we have $V = V^A \otimes I^B$ for some operator V^A acting on A. Since the unperturbed Hamiltonian H_0 does not include any interactions, additivity of the effective Hamiltonian implies $H_{\text{eff},n} = H^A_{\text{eff},n} \otimes I^B$, where $H^A_{\text{eff},n}$ is the effective low-energy Hamiltonian computed using only the subsystem A with the perturbation V^A, see Lemma 3.5 in Section 3.5. We conclude that all monomials in the decomposition of $H_{\text{eff},n}$ act trivially on B. By definition, $K_{n,C}$ does not depend on the variables $\epsilon_{u,v}$ with $(u,v) \notin C$, so we infer that $K_{n,C}$ acts trivially on B.

Suppose now that C consists of two disconnected subsets of edges C_1 and C_2. Choose $A = \Lambda(C_1)$ and $B = \Lambda(C_2)$. Again we set $\epsilon_{u,v} = 0$ for all $(u,v) \notin C$. Then we have $V = V^A \otimes I^B + I^A \otimes V^B$, where $V^A \otimes I^B$ is obtained from V by setting $\epsilon_{u,v} = 0$ for all $(u,v) \in C_2$. Similarly, $I^A \otimes V^B$ is obtained from V by setting $\epsilon_{u,v} = 0$ for all $(u,v) \in C_1$. Additivity of the effective Hamiltonian implies $H_{\text{eff},n} = H^A_{\text{eff},n} \otimes I^B + I^A \otimes H^B_{\text{eff},n}$, where $H^A_{\text{eff},n}$ and $H^B_{\text{eff},n}$ are the effective Hamiltonians computed using only the subsystems A and B with perturbations V^A and V^B respectively. It means that no monomial in $H_{\text{eff},n}$ contains variables $\epsilon_{u,v}$ from both C_1 and C_2 simultaneously. Since $K_{n,C}$ does not depend on the variables $\epsilon_{u,v}$ with $(u,v) \notin C$, we infer that $K_{n,C} = 0$.

The statement $K_{n,C} = 0$ for $|C| > n$ follows from the fact that $H_{\text{eff},n}$ contains only monomials of degree n. □

It is obvious from the proof that the linked cluster theorem applies to any operator-valued multivariate series that obeys the additivity property.

---

[3] Let us remark that absolute convergence of the univariate series $H_{\text{eff}} = \sum_{n=1}^{\infty} H_{\text{eff},n}\epsilon^n$ does not imply absolute convergence of the corresponding multivariate series, since different terms in the multivariate series may cancel out each other when combined into a single term $H_{\text{eff},n}$.

4.4 Local Schrieffer-Wolff trasformation

Applying the SW transformation described in Section 3 to many-body systems one must keep in mind that its generator S is a highly non-local operator even in the lowest orders of the perturbative expansion. This follows from the fact that S is a block-off-diagonal operator, that is $P_0 S P_0 = 0$ and $Q_0 S Q_0 = 0$, see Lemma 2.3. One can easily check that any block-off-diagonal operator must act non-trivially on every spin in the system. Indeed, block-off-diagonality implies $S = P_0 S + S P_0$. If one assumes that S acts trivially on some spin u, then $Q_{0,u} S Q_{0,u} = S Q_{0,u} \neq 0$. On the other hand, $Q_{0,u} S Q_{0,u} = Q_{0,u}(P_0 S + S P_0) Q_{0,u} = 0$ since $Q_{0,u} P_0 = P_0 Q_{0,u} = 0$. The non-locality of S is not a very serious drawback if the main object one is interested in is the effective low-energy Hamiltonian H_{eff}. Indeed, the linked cluster theorem proved in the previous section implies that all low-order corrections to H_{eff} are in fact local operators. On the other hand, the non-locality of S makes it more difficult to analyze properties of H_{eff}. In this section we get around this difficulty by employing a local version of the SW transformation developed by Datta et al [2]. To avoid a confusion between the two types of the SW transformation we shall refer to the direct rotation described in Sections 2,3 as a *global SW transformation*.

The local SW transformation is a unitary operator U that brings the perturbed Hamiltonian $H_0 + \epsilon V$ into an *approximately* block-diagonal form. Specifically, for any fixed integer $n \geq 0$ we shall choose $U = e^T$ where T is a degree-n polynomial in ϵ,

$$T = \sum_{q=1}^{n} T_q \, \epsilon^q, \quad T_q^\dagger = -T_q.$$

This polynomial will be chosen such that the transformed Hamiltonian $e^T(H_0 + \epsilon V)e^{-T}$ is block-diagonal if truncated at the order n. The definition of T is similar to the perturbative definition of S, see Section 3.2. We use the Taylor expansion of $\exp(\hat{T})$ to get

$$e^T(H_0 + \epsilon V)e^{-T} = H_0 + \sum_{j=1}^{n} \epsilon^j \left([T_j, H_0] + V^{(j-1)} \right) + \sum_{j=n+1}^{\infty} \epsilon^j \, V^{(j-1)}, \tag{4.18}$$

where $V^{(j)}$ is a certain polynomial function of $\hat{T}_1, \ldots, \hat{T}_{\min(j,n)}$ applied to H_0 or V. The precise form of this polynomial will be given in Eq. (4.27). Strictly speaking, $V^{(j)}$ should also carry a label n, but since n is fixed throughout this section, we shall only retain the label j.

The main difference between the local and global SW method is the inductive rule used to define the generators of the transformation. In the global SW method the generators S_j are fixed by demanding that S_j is block-off-diagonal while the j-th order contribution to the transformed Hamiltonian is block-diagonal, see Section 3.2. In the local SW method the generators T_j are fixed by demanding that T_j is a sum of local interactions (the range of interactions may depend on j) and each interaction is *locally* block-off-diagonal on the subset of spins it acts upon. For each local term in the expansion of $V^{(j-1)}$ we shall introduce the corresponding local term in T_j chosen such that the expansion of $[T_j, H_0] + V^{(j-1)}$ contains only block-diagonal terms.

To define the generators T_j formally let us introduce some notations. For any subset of spins $A \subseteq \Lambda$ define projectors onto the local low-energy and high-energy subspaces

$$P_A = \prod_{u \in A} P_{0,u} \quad \text{and} \quad Q_A = I - P_A. \tag{4.19}$$

Introduce superoperators $\mathcal{O}_A$ and $\mathcal{D}_A$ such that

$$\mathcal{O}_A(X) = P_A X\, Q_A + Q_A X\, P_A \quad \text{and} \quad \mathcal{D}_A(X) = P_A X\, P_A + Q_A X\, Q_A.$$

Clearly, $X = \mathcal{O}_A(X) + \mathcal{D}_A(X)$ for any operator X. We shall also need a local version of the superoperator $\mathcal{L}$, see Eq. (3.6). It can be chosen as

$$\mathcal{L}_A(X) = \int_0^\infty dt\, e^{-tH_{0,A}} Q_A X P_A - \int_0^\infty dt\, P_A X Q_A e^{-tH_{0,A}},$$

where $H_{0,A} = \sum_{u \in A} H_{0,u}$. Taking into account that $\|e^{-tH_{0,A}} Q_A\| \le e^{-\Delta t}$ one can easily check that the integral over t converges and

$$\|\mathcal{L}_A(X)\| \le \frac{\|X\|}{\Delta}. \tag{4.20}$$

In addition, for any operator X that acts non-trivially only on spins in A one has an identity

$$\mathcal{L}_A([H_0, X]) = [H_0, \mathcal{L}_A(X)] = \mathcal{O}_A(X). \tag{4.21}$$

Now we are ready to define the generators T_j. We begin by representing $V^{(j)}$ as a sum of local interactions,

$$V^{(j)} = \sum_{A \subseteq \Lambda} V_A^{(j)}.$$

Here $V_A^{(j)}$ acts non-trivially only on A (for example, one can use the expansion of $V^{(j)}$ in the generalized Pauli basis). Then we choose

$$T_j = \sum_{A \subseteq \Lambda} \mathcal{L}_A(V_A^{(j-1)}) \quad \text{for all } 1 \le j \le n. \tag{4.22}$$

Using the identity Eq. (4.21) one can easily check that for this choice of T_j

$$[T_j, H_0] + V^{(j-1)} = \sum_{A \subseteq \Lambda} \mathcal{D}_A(V_A^{(j-1)}) \quad \text{for all } 1 \le j \le n.$$

Accordingly, the transformed Hamiltonian can be written as

$$e^T (H_0 + \epsilon V) e^{-T} = H^{\langle n \rangle} + H_{\text{garbage}}, \tag{4.23}$$

where

$$H^{\langle n\rangle} = H_0 + \sum_{j=1}^{n} \epsilon^j \sum_{A\subseteq \Lambda} \mathcal{D}_A(V_A^{(j-1)}) \tag{4.24}$$

is a sum of local block-diagonal interactions, while

$$H_{\mathrm{garbage}} = \sum_{j=n+1}^{\infty} \epsilon^j \, V^{(j-1)} \tag{4.25}$$

includes all unwanted terms generated at the order $n+1$ and higher. Finally, we define the n-th order effective low-energy Hamiltonian as a restriction of $H^{\langle n\rangle}$ onto the subspace $\mathcal{P}_0$,

$$H_{\mathrm{eff}}^{\langle n\rangle} = P_0 H^{\langle n\rangle} P_0. \tag{4.26}$$

It is obvious from this construction that $H_{\mathrm{eff}}^{\langle n\rangle}$ is additive for perturbations describing two non-interacting disjoint systems, see Lemma 3.5. It follows that the Taylor coefficients of $H_{\mathrm{eff}}^{\langle n\rangle}$ obey the linked cluster property of Theorem 2.

For the later use let us give an explicit formula for the polynomial $V^{(j)}$. We have $V^{(0)} = V$ and

$$V^{(j-1)} = \sum_{q=2}^{j} \frac{1}{q!} \sum_{\substack{1\le j_1,\ldots j_q\le n\\ j_1+\ldots+j_q=j}} \hat{T}_{j_1}\cdots \hat{T}_{j_q}(H_0) + \sum_{q=1}^{j-1} \frac{1}{q!} \sum_{\substack{1\le j_1,\ldots j_q\le n\\ j_1+\ldots+j_q=j-1}} \hat{T}_{j_1}\cdots \hat{T}_{j_q}(V), \tag{4.27}$$

for all $j\ge 2$. Note that convergence of all above series in the limit $n\to\infty$ does not matter since we always consider some fixed order n. However, it can be shown [2] that the $n\to\infty$ limits of the series for T and $H_{\mathrm{eff}}^{\langle n\rangle}$ converge absolutely in the disk of radius $\epsilon_c \sim 1/N^2$.

Below we shall prove that the norm of H_{garbage} can be bounded by $O(N|\epsilon|^{n+1})$ for sufficiently small ϵ. Then we shall employ Lemma 4.1 and its Corollary 4.1 to show that the ground state of $H^{\langle n\rangle}$ belongs to the subspace $\mathcal{P}_0$ for sufficiently small ϵ. Combining the two results together we shall get the following theorem which can be regarded as an analogue of Theorem 4.7 in [2].

Theorem 3. *Let $H_{\mathrm{eff}}^{\langle n\rangle}$ be the n-th order low-energy effective Hamiltonian constructed using the local SW method. There exists a constant threshold*

$$\epsilon_c = \Omega(\Delta n^{-2}) \tag{4.28}$$

such that for all $|\epsilon| < \epsilon_c$ the ground state energy of $H_{\mathrm{eff}}^{\langle n\rangle}$ approximates the ground state energy of $H_0+\epsilon V$ with an error $\delta_n = O(N|\epsilon|^{n+1})$.

Given any perturbation V represented as a sum of local interactions, $V=\sum_{A\subseteq\Lambda} V_A$ we shall use the notation $\|V\|_1$ for the strength of V, that is,

$$\|V\|_1 = \max_{u\in\Lambda} \sum_{A\ni u} \|V_A\|.$$

All derivations below will implicitly use a bound

$$\sum_{A\, :\, A\cap M\neq\emptyset} \|V_A\| \le |M|\cdot \|V\|_1 \tag{4.29}$$

that holds for any operator $V=\sum_{A\subseteq\Lambda} V_A$ and for any subset of spins $M\subseteq\Lambda$. In particular, choosing $M=\Lambda$ we get a bound

$$\|V\| \le \sum_{A\subseteq\Lambda} \|V_A\| \le N\cdot \|V\|_1. \tag{4.30}$$

Applying Eq. (4.30) we can bound the norm of H_{garbage} as

$$\|H_{\mathrm{garbage}}\| = \|e^T(H_0+\epsilon V)\, e^{-T} - H^{\langle n\rangle}\| \le N \sum_{j=n+1}^\infty |\epsilon|^j \cdot \|V^{(j-1)}\|_1. \tag{4.31}$$

Thus our task is to get an upper bound on the norm $\|V^{(j)}\|_1$. To simplify notations we shall assume that the original perturbation V has strength $\|V\|_1=1$.

Lemma 4.2. *The operators T_j and $V^{(j-1)}$ are $(j+1)$-local Hamiltonians. There exists constants $\alpha,\beta>0$ such that*

$$\|V^{(j)}\|_1 \le \alpha \left(\frac{n^2}{\Delta\cdot\beta}\right)^j \tag{4.32}$$

for all $j\ge 0$.

Let us first explain how Theorem 3 follows from Lemma 4.2. Define $\rho_c=\Delta\beta n^{-2}$. Assume for simplicity that $\epsilon>0$. Substituting Eq. (4.32) into Eq. (4.31) one gets

$$\|H_{\mathrm{garbage}}\| \le \alpha N \sum_{j=n+1}^\infty \epsilon^j \rho_c^{1-j} \le 2\alpha\beta\Delta N n^{-2} (\epsilon/\rho_c)^{n+1} \tag{4.33}$$

provided that $\epsilon<\rho_c/2$. Using Corollary 4.1 of Lemma 4.1 and the fact that $V^{(j-1)}$ is $(j+1)$-local Hamiltonian we conclude that the ground state of $H^{\langle n\rangle}$ belongs to the subspace $\mathcal{P}_0$ whenever

$$\sum_{j=1}^n 2^{3+j}\cdot|\epsilon|^j\cdot\|V^{(j-1)}\|_1 < \Delta.$$

Using the bound Eq. (4.32) we get

$$\sum_{j=1}^n 2^{3+j}\cdot|\epsilon|^j\cdot\|V^{(j-1)}\|_1 \le 16\alpha\epsilon \sum_{j=0}^\infty (2\epsilon/\rho_c)^j \le 32\alpha\epsilon < \Delta$$

provided that $\epsilon < \rho_c/4$ and $32\alpha\epsilon < \Delta$. If we choose

$$\epsilon_c = \min\left[\frac{\Delta\beta}{4n^2}, \frac{\Delta}{32\alpha}\right]$$

then for all $\epsilon < \epsilon_c$ the ground state of $H^{\langle n\rangle}$ belongs to the subspace $\mathcal{P}_0$ and $\|H_{\text{garbage}}\| = O(N\epsilon^{n+1})$. Theorem 3 now follows from the fact that $H^{\langle n\rangle} + H_{\text{garbage}}$ has the same spectrum as $H_0 + V$. In the rest of the section we prove Lemma 4.2.

Proof of Lemma 4.2. Let us first analyze locality of T_j and $V^{(j-1)}$.

Proposition 4.1. *T_j is a $(j+1)$-local anti-hermitian Hamiltonian. $V^{(j-1)}$ is a $(j+1)$-local Hamiltonian.*

Proof. We shall use the fact that for any a-local Hamiltonian X and b-local Hamiltonian Y the commutator $[X, Y]$ is at most $(a+b-1)$-local. By assumption, $V^{(0)} = V$ is a 2-local Hamiltonian. Using Eq. (4.22) we conclude that T_1 is a 2-local Hamiltonian (anti-hermitian). Let us use induction to prove that T_j and $V^{(j-1)}$ are $(j+1)$-local. Indeed, from Eq. (4.27) one can see that $V^{(j-1)}$ is a sum of terms proportional to $\hat{T}_{j_1}\cdots\hat{T}_{j_q}(H_0)$ with $j_1 + \ldots + j_q = j$, $q \ge 2$, and terms proportional to $\hat{T}_{j_1}\cdots\hat{T}_{j_q}(V)$ with $j_1 + \ldots + j_q = j-1$, $q \ge 1$. The terms of the first type are at most k'-local with $k' = j_1 + \ldots + j_q + 1 = j+1$. The terms of the second type are at most k''-local with $k'' = 2 + j_1 + \ldots + j_q = j+1$. Thus $V^{(j-1)}$ is $j+1$-local. Using Eq. (4.22) we conclude that T_j is $j+1$-local. □

Recall that the truncated Hamiltonian $H^{\langle n\rangle}$ is computed using a *finite* number of generators $T_1, \ldots, T_n$. Thus *any* generator T_j is at most $(n+1)$-local.

Proposition 4.2. *Let W be an r-local Hamiltonian. Then for any $j \le n$ one has*

$$\|\hat{T}_j(W)\|_1 \le \frac{2(r+n+1)}{\Delta}\,\|V^{(j-1)}\|_1 \cdot \|W\|_1. \tag{4.34}$$

Proof. Indeed, expand T_j and W as a sum of local operators,

$$T_j = \sum_{M\subseteq\Lambda} T_{j,M}, \quad W = \sum_{A\subseteq\Lambda} W_A,$$

where $|M| \le j+1 \le n+1$, see Proposition 4.1, and $|A| \le r$ since W is r-local. Here T_j is related to $V^{(j-1)}$ by Eq. (4.22), that is,

$$V^{(j-1)} = \sum_{M\subseteq\Lambda} V_M^{(j-1)}, \quad T_{j,M} = \mathcal{L}_M(V_M^{(j-1)}), \quad \|T_{j,M}\| \le \frac{1}{\Delta}\,\|V_M^{(j-1)}\|.$$

Let $u \in \Lambda$ be the spin that maximizes the norm $\|\hat{T}_j(W)\|_1$. Then

$$\begin{aligned}
\|\hat{T}_j(W)\|_1 &\le 2\sum_{M\ni u}\ \sum_{A\,:\,A\cap M\neq\emptyset} \|T_{j,M}\|\cdot\|W_A\| + 2\sum_{A\ni u}\ \sum_{M\,:\,M\cap A\neq\emptyset} \|T_{j,M}\|\cdot\|W_A\| \\
&\le \frac{2}{\Delta}\sum_{M\ni u}\ \sum_{A\,:\,A\cap M\neq\emptyset} \|V_M^{(j-1)}\|\cdot\|W_A\| + \frac{2}{\Delta}\sum_{A\ni u}\ \sum_{M\,:\,M\cap A\neq\emptyset} \|V_M^{(j-1)}\|\cdot\|W_A\| \\
&\le \frac{2}{\Delta}\|W\|_1 \sum_{M\ni u} |M|\cdot\|V_M^{(j-1)}\| + \frac{2}{\Delta}\|V^{(j-1)}\|_1 \sum_{A\ni u} |A|\cdot\|W_A\| \\
&\le \frac{2(r+n+1)}{\Delta}\,\|V^{(j-1)}\|_1\cdot\|W\|_1.
\end{aligned}$$

□

Now we can apply Proposition 4.2 to bound the norm of any term in Eq. (4.27). Note that $V^{(j-1)}$ is composed of two types of terms. We have terms proportional to $A_{\mathbf{j}} = \hat{T}_{j_1}\cdots\hat{T}_{j_q}(H_0)$ with $1 \le j_1,\ldots,j_q \le n$, $j_1+\ldots+j_q = j$, and terms proportional to $B_{\mathbf{j}} = \hat{T}_{j_1}\cdots\hat{T}_{j_q}(V)$ with $1 \le j_1,\ldots,j_q \le n$, $j_1+\ldots+j_q = j-1$. Note that applying q commutators $\hat{T}_{j_1}\cdots\hat{T}_{j_q}$ to H_0 or V we can produce at most $O(qn)$-local operator. Applying Proposition 4.2 we get

$$\begin{aligned}
\|A_{\mathbf{j}}\|_1 &\le O(n\Delta^{-1})^q\, q^q\cdot\Delta\cdot\|V^{(j_1-1)}\|_1\cdots\|V^{(j_q-1)}\|_1, \\
\|B_{\mathbf{j}}\|_1 &\le O(n\Delta^{-1})^q\, q^q\cdot\|V^{(j_1-1)}\|_1\cdots\|V^{(j_q-1)}\|_1
\end{aligned}\tag{4.35}$$

where we have taken into account that $\|V\|_1 = 1$ and $\|H_0\|_1 = O(\Delta)$. Let us introduce an auxiliary quantity

$$\chi_j = \|V^{(j-1)}\|_1, \quad j \ge 1. \tag{4.36}$$

Using Eqs. (4.27,4.35) we can get an upper bound $\chi_j \le \mu_j$, where

$$\mu_1 = \chi_1 = \|V\|_1 = 1$$

and μ_j, $j \ge 2$, are defined inductively from

$$\mu_j = \Delta\sum_{q=2}^{j} c^q \sum_{j_1+\ldots+j_q=j} \mu_{j_1}\cdots\mu_{j_q} + \sum_{q=1}^{j-1} c^q \sum_{j_1+\ldots+j_q=j-1} \mu_{j_1}\cdots\mu_{j_q}, \tag{4.37}$$

where $c \equiv O(n\Delta^{-1})$. Here we have taken into account that $q^q/q! = O(1)^q$ and omitted the constraint $j_1,\ldots,j_q \le n$ since we are interested in an upper bound on χ_j (note that adding this constraint can only make μ_j to grow more slowly with j). In order to get an upper bound on μ_j define an auxiliary Taylor series

$$\mu(z) = \sum_{j=1}^{\infty} \mu_j\, z^j. \tag{4.38}$$

Inspecting the recursive equation Eq. (4.37) one can easily convince oneself that $\mu(z)$ has to obey the following equation

$$\mu = \Delta\left(\frac{1}{1-c\mu} - 1 - c\mu\right) + z\left(\frac{1}{1-c\mu} - 1\right) + z.$$

Solving this equation one can easily find the inverse function:

$$z(\mu) = \mu - \mu^2(c + \Delta c^2).$$

Clearly $z(\mu)$ is analytic in the entire complex plane. Solving the quadratic equation and choosing the branch for which $\mu(0) = 0$ one gets

$$\mu(z) = \frac{1}{2(c+\Delta c^2)}\left(1 - \sqrt{1 - 4z(c+\Delta c^2)}\right).$$

Clearly $\mu(z)$ is analytic in a disk $|z| < z_0$ where

$$z_0 = \frac{1}{4(c+\Delta c^2)} \ge \frac{\beta\Delta}{n^2}$$

for some constant $\beta > 0$. Here we have taken into account that $c = O(n\Delta^{-1})$. Using the Cauchy integral formula for $\mu(z)$ one gets

$$\mu_j = \frac{1}{2\pi i}\oint_{|z|=z_0/2} \frac{\mu(z)}{z^{j+1}}\, dz$$

which yields

$$\mu_j \le \alpha\left(\frac{\beta\Delta}{n^2}\right)^{1-j}$$

for some constant $\alpha > 0$. The lemma is proved. □

4.5 Equivalence between the local and global SW theories

In this section we prove Theorem 1. The key idea of the proof is to construct a unitary operator e^K acting on the low-energy subspace $\mathcal{P}_0$ that transforms the n-th order effective low-energy Hamiltonian obtained using the local SW method to the one obtained using the global SW method with an error $O(N|\epsilon|^{n+1})$ in the operator norm. We illustrate the relationship between the two low-energy theories on Fig. 4. Once the desired unitary transformation e^K is constructed, Theorem 1 follows directly from Theorem 3. To introduce the notations let us first consider the limit $n \to \infty$. Let

$$S = \sum_{j=1}^{\infty} S_j\, \epsilon^j \quad \text{and} \quad T = \sum_{j=1}^{\infty} T_j\, \epsilon^j \tag{4.39}$$

$$\begin{tikzcd}
& H_0 + \epsilon V \arrow[dl, "\text{Global SW}"', "e^S"] \arrow[dr, "e^T"', "\text{Local SW}"] & \\
P_0\, e^S (H_0 + \epsilon V) e^{-S} P_0 & & P_0\, e^T (H_0 + \epsilon V) e^{-T} P_0 \arrow[ll, "e^K"']
\end{tikzcd}$$

Figure 4: Correspondence between the high-energy theory $H_0 + \epsilon V$ and the effective low-energy theories obtained using the global and the local Schrieffer-Wolff transformations. The unitary operator e^K defined on the low-energy subspace $\mathcal{P}_0$ maps the two effective low-energy Hamiltonians to each other.

be generators of the SW transformation calculated using the global rule (S) and the local rule (T). Here we regard S and T as formal Taylor series. Let

$$H^{\mathrm{gl}} = e^S (H_0 + \epsilon V) e^{-S} \quad \text{and} \quad H^{\mathrm{loc}} = e^T (H_0 + \epsilon V) e^{-T}$$

be the corresponding transformed Hamiltonians which we also consider as formal Taylor series. Let $H^{\mathrm{loc},\langle n\rangle}$ and $H^{\mathrm{gl},\langle n\rangle}$ be the Hamiltonians obtained from H^{loc} and H^{gl} respectively by truncating the series at the order n.

Theorem 4. *Let*

$$L = P_0\, H^{\mathrm{loc},\langle n\rangle} P_0 \quad \textit{and} \quad M = P_0\, H^{\mathrm{gl},\langle n\rangle} P_0$$

be the effective order-n Hamiltonians on the low-energy subspace obtained by the local and the global SW methods. There exists a constant β depending only on n, Δ, and the maximum degree of the interaction graph such that

$$\| M - e^K L e^{-K} \| \le \beta N |\epsilon|^{n+1} \quad \textit{for all } |\epsilon| \le 1 \tag{4.40}$$

for some unitary operator e^K acting on the subspace $\mathcal{P}_0$.

A natural way to define the desired unitary transformation e^K is

$$e^K = e^S\, e^{-T}. \tag{4.41}$$

Indeed, one should expect that e^{-T} maps the local low-energy to the high-energy theory and e^S maps the high-energy theory to the global low-energy theory. The main difficulty in using Eq. (4.41) is that (i) it defines a unitary transformation on the entire Hilbert space $\mathcal{H}$ while we expect the two theories to be close only on the low-energy subspace $\mathcal{P}_0$; (ii) the formal series K, S, and T may be divergent.

The proof of Theorem 4 goes as follows. We shall regard Eq. (4.41) as a definition of a formal Taylor series

$$K = \sum_{j=1}^{\infty} K_j \, \epsilon^j$$

Here K_j are some operators acting on the entire Hilbert space $\mathcal{H}$. We will show that operators K_j are actually block-diagonal, so we can apply the transformation e^K on the subspace $\mathcal{P}_0$ only, see Lemma 4.3, even if one uses a truncated version of K. Next we shall make use of the fact that the SW operators e^S and e^T have (weak) multiplicativity properties, see Lemma 2.4. It will allow us to prove multiplicativity for e^K and thus additivity of K, see Eqs. (4.46). Next we shall exploit the additivity of K to show that the series for K obeys the linked cluster condition analogous to Theorem 2. Finally, we shall construct the desired transformation mapping the local theory to the global theory as $\exp(K^{\langle n \rangle})$, where $K^{\langle n \rangle} = \sum_{j=1}^n K_j \, \epsilon^j$. Lemma 4.4 shows that this transformation indeed does the right job.

Lemma 4.3. *Suppose H_0 has a positive spectral gap Δ between $\mathcal{P}_0$ and $\mathcal{P}_0^\perp$. Then all generators K_j are block-diagonal.*

Proof. By definition we have

$$H^{\mathrm{gl}} = e^K \, H^{\mathrm{loc}} \, e^{-K} \tag{4.42}$$

and both operators H^{gl}, H^{loc} are block-diagonal. It is assumed here that H^{gl} and H^{loc} are formal Taylor series in ϵ Let us multiply Eq. (4.42) by P_0 and Q_0 on the left and on the right respectively. Taking into account that H^{gl} and H^{loc} are block-diagonal, and using formal Taylor series $H^{\mathrm{loc}} = \sum_{j=0}^{\infty} H_j^{\mathrm{loc}} \, \epsilon^j$ with $H_0^{\mathrm{loc}} = H_0$ one obtains

$$P_0[K_j, H_0]Q_0 + P_0 f(K_1, \ldots, K_{j-1}, H_1^{\mathrm{loc}}, \ldots, H_j^{loc})Q_0 = 0 \quad \text{for all } j \geq 1, \tag{4.43}$$

where $f(K_1, \ldots, K_{j-1}, H_1^{\mathrm{loc}}, \ldots, H_j^{loc})$ is some polynomial obtained from the expansion of the exponent in Eq. (4.42). Let us use induction in j to show that K_j is block-diagonal. Indeed, suppose we have already proved that $K_1, \ldots, K_{j-1}$ are block-diagonal. Then the term

$$P_0 f(K_1, \ldots, K_{j-1}, H_1^{\mathrm{loc}}, \ldots, H_j^{loc})Q_0$$

in Eq. (4.43) vanishes and we can rewrite Eq. (4.43) as

$$(P_0 K_j Q_0)(Q_0 H_0 Q_0) = (P_0 H_0 P_0)(P_0 K_j Q_0). \tag{4.44}$$

If $|\psi\rangle \in Q_0$ is any eigenvector of $Q_0 H_0 Q_0$ with an eigenvalue λ, then Eq. (4.44) implies that a state $(P_0 K_j Q_0)\,|\psi\rangle$ is an eigenvector of $P_0 H_0 P_0$ with the same eigenvalue λ. On the other hand, $(P_0 K_j Q_0)\,|\psi\rangle \in \mathcal{P}_0$. It contradicts to the spectral gap assumption unless $(P_0 K_j Q_0)\,|\psi\rangle = 0$. Since eigenvectors of $Q_0 H_0 Q_0$ span the entire subspace Q_0, we conclude that $P_0 K_j Q_0 = 0$. Since K is anti-hermitian, it implies $Q_0 K_j P_0 = 0$, that is, K_j is block-diagonal. $\square$

Let us now prove that the restriction of K onto the $\mathcal{P}_0$ subspace obeys the additivity property: if one partitions the lattice Λ into two disjoint parts, $\Lambda = AB$, such that $V = V_A + V_B$ then $K = K_A + K_B$ (only on the subspace $\mathcal{P}_0$). Note that the generator T constructed using the local SW method is additive by construction, so we have $T = T_A + T_B$ on the entire Hilbert space (not only on the subspace $\mathcal{P}_0$). On the other hand, weak multiplicativity of the direct rotation, see Lemma 2.4, implies

$$P_0\, e^S = P_0\, e^{S_A+S_B}. \tag{4.45}$$

Since $e^K = e^S e^{-T}$, we conclude that the restriction of K onto the subspace $\mathcal{P}_0$ is additive, that is,

$$e^{-K}\, P_0 = e^{-K_A-K_B}\, P_0 \tag{4.46}$$

By abuse of notations let us identify K, K_A, K_B with their restrictions of the on the subspace $\mathcal{P}_0$. Then we have $e^{-K} = e^{-K_A}e^{-K_B} = e^{-K_A-K_B}$. Taking the logarithm we obtain the desired additivity property, $K = K_A + K_B$. It implies that the series for K obeys the linked cluster condition, see Theorem 2. Using the same notations as in the statement of Theorem 2 we conclude that

$$K_j = \sum_{C\subseteq \mathcal{E}} K_{j,C},$$

where $K_{j,C}$ acts only on $\Lambda(C)$ and $K_{j,C} = 0$ unless $|C| \le j$ and C is a connected subset of edges. Define an interaction strength of K as

$$J_K = \max_{u\in\mathcal{L}} \max_{j=1,\ldots,n} \sum_{C\ni u} \|K_{j,C}\|. \tag{4.47}$$

We claim that

$$J_K = O(1), \tag{4.48}$$

that is, J_K has an upper bound independent of N. Indeed, assuming that the interaction graph has degree $d = O(1)$, the number of linked clusters of size $\le n$ containing a given vertex u can be upper bounded by $d^{O(n)} = O(1)$. Additivity of K implies that we can compute $K_{j,C}$ by turning off all interactions $V_{u,v}$, $(u,v) \notin C$. It leaves us with a subgraph with at most $N' = 2|C| \le 2j \le 2n = O(1)$ sites. Since the number of spins is $O(1)$, any operator $K_{j,C}$ is a constant-degree polynomial with constant-bounded coefficients, so that $\|K_{j,C}\| = O(1)$. Theorem 4 now follows from the following lemma.

Lemma 4.4. *Let K, L, M be formal operator-valued Taylor series acting on the subspace $\mathcal{P}_0$ such that K is anti-hermitian, $K(0) = 0$, and*

$$M = e^K L e^{-K}. \tag{4.49}$$

For any integer $n = O(1)$ define truncated series

$$\tilde{K} = \sum_{j=1}^n K_j\, \epsilon^j, \quad \tilde{L} = \sum_{j=0}^n L_j\, \epsilon^j, \quad \tilde{M} = \sum_{j=0}^n M_j\, \epsilon^j \tag{4.50}$$

and a truncation error

$$\delta = \|\tilde{M} - e^{\tilde{K}}\tilde{L}\, e^{-\tilde{K}}\|. \tag{4.51}$$

Suppose K, L, M obey the linked cluster property and have constant-bounded interaction strength, $J_K, J_L, J_M = O(1)$. Then

$$\delta \le O(1)N|\epsilon|^{n+1} \quad \textit{for any } |\epsilon| \le 1. \tag{4.52}$$

Proof. Introduce a truncated version of a transformed operator $e^{\tilde{K}}\tilde{L}\, e^{-\tilde{K}}$, namely,

$$\Theta = \tilde{L} + \sum_{j=1}^{n} \frac{1}{j!}\, [\tilde{K}, \cdot]^j \tilde{L}.$$

The assumptions that K obeys the linked cluster property and $K(0) = 0$ imply that $i\tilde{K}$ can be regarded as a local Hamiltonian with interaction strength upper bounded by $J_K \sum_{j=1}^n |\epsilon|^j = O(|\epsilon|)$. Similarly, $\tilde{L}$ can be regarded as a local Hamiltonian with interaction strength $O(1)$. Using Lemmas 1,2 from [24] one gets an approximation

$$\|e^{\tilde{K}}\tilde{L}\, e^{-\tilde{K}} - \Theta\| \le \frac{1}{(n+1)!}\, \|\, [\tilde{K}, \cdot]^{n+1}\tilde{L}\, \| \le O(1)N|\epsilon|^{n+1}. \tag{4.53}$$

Therefore it suffices to show that

$$\|\tilde{M} - \Theta\| \le O(1)N|\epsilon|^{n+1}. \tag{4.54}$$

Expanding the multiple commutators in Θ we get a linear combination of terms

$$\frac{1}{j!}\, \epsilon^{q_1+q_2+\ldots+q_j+q}\, \hat{K}_{q_1}\hat{K}_{q_2}\cdots\hat{K}_{q_j}(L_q), \quad 1 \le q_1, \ldots, q_j \le n, \quad 1 \le j \le n, \quad 1 \le q \le n.$$

Let us call a term as above *good* if the total power of ϵ is at most n, that is, $q_1 + q_2 + \ldots + q_j + q \le n$. Otherwise let us call such a term *bad*. Using the condition Eq. (4.49) one can easily check that the sum of all good terms in Θ equals $\tilde{M}$. Thus we get a bound

$$\|\tilde{M} - \Theta\| \le |\epsilon|^{n+1}\, \#\{\text{bad terms}\}\, \max \|\hat{K}_{q_1}\hat{K}_{q_2}\cdots\hat{K}_{q_j}(L_q)\|. \tag{4.55}$$

Clearly for a constant n the total number of terms in Θ is $O(1)$ and so the number of bad terms is $O(1)$. Applying again Lemma 2 from [24] and taking into account that the Taylor coefficients K_{q_i} and L_q are local Hamiltonians with interaction strength $O(1)$ we get a bound

$$\max \|\hat{K}_{q_1}\hat{K}_{q_2}\cdots\hat{K}_{q_j}(L_q)\| \le O(1)N.$$

Therefore $\|\tilde{M} - \Theta\| \le O(1)N|\epsilon|^{n+1}$. □
